This presents a statistical study and discussion of 1,139 case histories over a period of ten years at the New York Hospital. A critical evaluation is given the reader of results from both the medical and the surgical treatment of the disease without giving too many descriptive details of the therapy itself. The book is divided into two parts, on medical and on surgical treatment. In the medical section there is discussion of both ambulatory and hospital treatment. Considerable emphasis is placed on the question of hemorrhage and of malignancy in gastric ulcer. In addition there is some mention of an attempt to deal with the psychologic problems involved. The surgical section is of course chiefly concerned with the results obtained with gastroenterostomy as compared with gastric resection. No attempt is made to influence the reader as to the method of choice, but the authors do feel that in resection a moderate resection is the operation of choice. There is, of course, a chapter on surgery for perforations and an excellent chapter on the effects of operation on gastric secretion. The book closes with a survey of the literature on the subject and finally a discussion and summary of the material covered in the book. A bibliography of the literature referred to is given. The authors do not purport to offer the final answer or give a cure-all. Rather they are attempting to help clarify many controversial facts to aid one in the therapy of what is at best a difficult disease to treat. Certainly we are reminded of the fact that peptic ulcer is still a serious problem and that much remains to be done to untangle the many ramifications of the therapy of peptic ulcer.

An Introduction to Pharmacology and Therapeutics. By J. A. Gunn, M.A., M.D., D.Sc., Professor of Therapeutics and Director of the Nuffield Institute for Medical Research, University of Oxford. Seventh edition. Fabrikoid. Price, $2.25. Pp. 268. New York & London: Oxford University Press, 1941.

The first edition of this delightfully written pocket size synopsis of pharmacology appeared in 1929. Its popularity both in the British Isles and in this country has given impetus to frequent revisions. The present edition, like the previous ones, summarizes in an authoritative manner the principal actions and uses of the more important drugs. The discussions in many instances are briefer than those found in the comparable American publication Useful Drugs. The emphasis in the book has been placed on drugs official in the British Pharmacopeia or the United States Pharmacopeia. Unfortunately, although the book was actually revised in 1943, many of the newer and widely used useful drugs are omitted. Desoxyephedrine ("Pervitin," "Methedrine"), which was first used in Europe, is not mentioned; quaternary ammonium antiseptics are omitted; the discussion of the sulfonamides is extremely brief and the newer ones, such as succinylsulfathiazole and sulfamerazine, are not mentioned; no discussion of the antibiotics is to be found, although the omission of penicillin is not surprising since the published clinical information on this drug was scant at the time this edition was prepared. The book's chief usefulness is as a readable summary of conservative pharmacology and as such will prove useful both to the student and to the practicing physician.

The Reticulo-Endothelial System in Sulfonamide Activity. By Frank Thomas Maher, Ph.D., Assistant Professor of Pharmacognosy and Pharmacy. Contribution from the Department of Pharmacology, Materia Medica and Therapeutics in the College of Medicine. Illinois Monographs in the Medical Sciences, Vol. V, Nos. 1-2. Paper. Price, $2.50. Pp. 232, with 23 Illustrations. Urbana: University of Illinois Press, 1944.

This interesting monograph was presented in 1941 as a dissertation for the degree of doctor of philosophy in pharmacology in the Graduate School of the University of Illinois. It is an important contribution to the role of "defense mechanisms" in chemotherapy. The "defense mechanisms" of the body against bacterial infection depend in part on the activity of the reticuloendothelial system. The many careful experiments reported in this study show that blocking the reticuloendothelial system (by thorotrast) reduces the resistance of animals to infection with Staphylococcus aureus, depresses conjugation of sulfanilamide and sulfathiazole and reduces the chemotherapeutic effectiveness of sulfathiazole in animals infected with Staphylococcus aureus. It is therefore concluded that reticuloendothelial activity is necessary to effective sulfonamide chemotherapy. The large bibliography of six hundred and twelve references refers chiefly to bacterial infections and the sulfonamides. The illustrations offer evidence of the successful blocking of the reticuloendothelial system by means of thorotrast. While the monograph exhaustively reports a large and interesting group of experiments, it affords little information of significance to the "practical" physician. However, it adds materially to the growing body of evidence showing the importance of the reticuloendothelial system in resisting infection and in contributing to the effectiveness of chemotherapeutic agents. Many workers have demonstrated the importance of the reticuloendothelial system, particularly the spleen, in relation to trypanosome infections and the chemotherapeutic effectiveness of arsenical drugs. Little information has been made available as to methods whereby the reticuloendothelial system can be stimulated to afford increasing resistance to bacterial infection. The work of Bogomolets and his Russian collaborators suggests methods that may become of "practical" interest.

Keys to the Anopheline Mosquitoes of the World With Notes on Their Identification, Distribution, Biology, and Relation to Malaria. Prepared for the Preventive Medicine Division, Office of the Surgeon General, U. S. Army. By Paul F. Russell, M.D., M.P.H., Lieut. Colonel, Medical Corps, A. U. S., Lloyd E. Rozeboom, B.S., Sc.D., and Alan Stone, B.S., Ph.D. Paper. Pp. 152, with 10 Illustrations. Philadelphia: American Entomological Society, Academy of Natural Sciences, 1943.

This excellent handbook was prepared especially for use by the Army in its education program to keep pace with the global expansion of the war. The introduction includes a brief history of the discoveries of mosquitoes as vectors of disease and comments on how Anopheles with particular habits may be related to malaria in a community. Chapter II gives a simple but effective outline on mosquito identification, which is well illustrated with appropriate drawings. The keys in the following chapters are largely borrowed from previous works. The chapters of keys are Anopheles of Canada, the United States and Northern Mexico, Anopheles of Central America, Anopheles of Europe, North Africa and the Near East, Anopheles of South and Central Africa, Anopheles of Asia, except the Philippines, southern Asia, northern Asia and the Malayan region, Anopheles of the Philippines and Anopheles of the Australian region. Following the key in each chapter the mosquitoes are listed alphabetically and notes on their identification, distribution, biology and relation to malaria are given. Another chapter summarizes the known vectors of malaria for specific localities of the world. The list of references is extensive. The index to specific and subspecific names is adequate for the volume. This practical volume will undoubtedly find wide application by those who have occasion to identify anopheline mosquitoes in any part of the world.

Voenno-meditsinskiy sbornik. 1. [Compiled by] Voenno-Sanitarnaya Komissiya. [Collection of Articles on Military Medicine.] Paper. Price, 8 rubles. Pp. 160, with Illustrations. Moskva & Leningrad: Izdatelstvo Akademii Nauk, SSSR, 1944.

The volume contains several papers on the effects of amphetamine on fliers, on the effect of nitrogen concentration in fliers, on a new biochemical preparation for acceleration of wound healing—an autolysate of brewers' yeast—and so on. The symposium is of the type that does not rate a review in THE JOURNAL.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

EFFECT OF SULFONAMIDES AND VITAMINS ON THE TEETH

To the Editor:—A dentist maintains that the sulfonamide compounds, sulfanilamide in particular, has a softening effect on the teeth. A patient with pharyngitis was given sulfanilamide two years ago and the decay of some of his teeth has been attributed to the sulfonamide compounds. The dentist is now prescribing vitamins to a patient who has had a liberal mixed diet and says he will have to replace all fillings because of the damage done to the teeth by the use of the sulfonamide compounds. What is the best opinion concerning the use of sulfonamide compounds for pharyngitis and what effect if any can sulfonamide compounds have on teeth? In what manner can vitamins repair brittle or soft teeth?

S. A. Kleger, M.D., Astoria, Ore.

ANSWER.—In a large group of patients given sulfanilamide for various reasons, no effects on the teeth have been observed or reported. There is no mechanism known whereby sulfonamide compounds could affect the structure of the teeth or modify the process of dental decay.

The description brittle or soft teeth is indefinite. Imperfect calcification of the teeth can occur only during their developmental period. Decalcification of the enamel, on the other hand, results only from the local action of acids on the surface of the tooth. Perhaps reference is made to dental caries: the relation of sulfanilamide to this condition is not known.

The use of vitamins to prevent or treat dental caries has been proved to be ineffective in a number of investigations. The enamel of the tooth, which is the first dental structure attacked by decay, is avascular and acellular and does not have power of regeneration or repair. Removal of the decay and replacement of the lost structure by proper restoration is the only effective treatment.

HAZARDS OF EXPLOSIVE ANESTHESIA

To the Editor:—What precautions should be taken in the use of explosive anesthetics? Is the use of cyclopropane and ethylene without intercouplers or insulation safe? What are the minimum safeguards? Is cyclopropane as safe as nitrous oxide, oxygen and ether, as some authors state? I would like to install the legitimate requirements on two new Heidbrinks and a Foregger machine.

V. M. McCartney, M.D., Warren, Ohio.

ANSWER.—In order to produce a fire or explosion in the operating room, two conditions are necessary: there must be an ignitible mixture of vapors or gases, and such a mixture must come in contact with a source of heat sufficient to ignite it. A mixture to be ignitible must contain the ignitible substance (usually a hydrocarbon compound such as alcohol, ether, ethylene or cyclopropane) and an adequate amount of available oxygen. Sources of heat may be furnished by open flames such as gas burners or alcohol lamps, by cauteries, by partially broken connections and other imperfections of electric surgical instruments and lights and by static sparks. It should be remembered that gases compressed in containers under high pressure may explode without the aid of ignition when the pressure is higher than the strength of the container. Absolute protection would forbid the presence of any ignitible mixture, a requirement as practical as it would be to forbid the use of illuminating gas in kitchens or of gasoline in automobiles. Intelligent application of precautions which are obvious can reduce the hazard in operating rooms to a point no more dangerous than is the use of a gas range, a water heater or an automobile. Any added hazard in the operating room as compared with the kitchen has to do with the presence of superabundant oxygen to promote combustion. Nitrous oxide supports combustion almost as well as does oxygen.

Certain of the obvious precautions may be listed categorically. 1. Open flames (gas, alcohol) and glowing fire (smokers) are not permissible. 2. All electric equipment (lighting, cauteries, electrosurgical) should be inspected frequently and kept in perfect condition. 3. Containers and apparatus for the control of volatile substances and compressed gases, including oxygen and nitrous oxide, should be inspected frequently and kept in proper leakless operating condition. 4. Oxygen and nitrous oxide or their mixtures must be looked on as superabundant sources of support for combustion.

More specific "rules for the anesthetist" are often laid down, but these cannot replace an ever present awareness of the possibilities and recognition of the laws of physics. Such rules are: 1. Use only noninflammable agents when the cautery or other sources of ignition must be applied near the face or in the air passages. Be sure that infinitesimal quantities of inflammable agents are not inadvertently mixed with oxygen and nitrous oxide under such circumstances. 2. If the anesthetist is capable of using a closed technic (carbon dioxide absorption) without leaks, the cautery, electric knives and so on may be used on distant parts of the body when inflammable agents are employed. 3. Precautions regarding hazard from static sparks have been controversial. Engineers answer the question academically by advising complete "grounding" of all objects in contact with or in the vicinity of the patient. When they become familiar with operating room conditions, however, they realize that complete grounding is impossible to achieve in the operating room. Humid atmosphere, radiated atmosphere, intercouplers (special metal connectors between all objects) and other safeguards have been suggested. Experience to date is not convincing that any of these affords a more practical safeguard from static sparks than if the anesthetist makes it a rule to place his hands in contact with the patient, apparatus and table in preparing to anesthetize and maintains contact between all objects within the area contaminated by ignitible mixtures throughout the administration.

DEVELOPMENT OF RED BLOOD CELLS

To the Editor:—What is the normal percentage of normoblasts or erythroblasts, if any, present in the cord blood of a living or recently dead 4½ to 7 months fetus? Is a normoblast the same as an erythroblast? If not, in what respect do they look different under the microscope?

Charles J. Marshall, M.D., Binghamton, N. Y.

ANSWER.—According to the great majority of investigators there are two generations of red blood cells in all vertebrates. The first of these is called the primitive or transitory or temporary generation in which the final product is a spherical, nucleated, hemoglobin containing cell—the first oxygen carrier of the embryo. In the mammals it develops almost exclusively in the yolk sac. The permanent or definitive red blood cell generation in the embryo develops in several successive sites beginning with the liver and ending with the bone marrow. Its final product is the non-nucleated erythrocyte, which is identical in all respects with the erythrocyte or erythroplastid of the postnatal and adult mammal. According to some investigators all precursors of normal erythrocytes of both generations should be called erythroblasts and the specific stage of blood cell formation should be indicated by a modifying adjective such as primitive basophile erythroblast or definitive basophile erythroblast, and similarly for polychromatic and orthochromatic erythroblasts of both generations. According to this terminology the orthochromatic erythroblast is also called a normoblast. This is a relatively small cell in the definitive generation with an eosin staining cytoplasm of the same color as that of the mature non-nucleated erythrocyte. There are a few authorities, however, who use the term normoblast for all of the precursors of the erythrocytes of the definitive generation. These authorities thus speak of basophile normoblasts, polychromatic normoblasts and normoblasts.

The greatest difference in appearance between the nucleated erythrocytes of the primitive and definitive generations is in the size of the cells. The primitive erythrocytes are large and according to some investigators they are comparable in appearance with the megaloblasts of pernicious anemia.

In early embryos, all erythrocytes are nucleated cells of the primitive generation. The number of nucleated erythrocytes in the embryonic blood of man diminishes progressively during the remainder of gestation. In the latter part of fetal life all of the nucleated erythrocytes are of the definitive generation. The only figures available for the stages indicated in the question are as follows: A 362 Gm. embryo with a menstrual history of 17 weeks had counts of 12,000 nucleated erythrocytes, total red blood cells of 3½ million and 4,000 white blood cells in the cord blood. A fetus of 440 Gm. with a menstrual history of 24 weeks had counts of 3,500 nucleated erythrocytes, total red blood cell count of 2,940,000 and 3,500 white blood corpuscles.

The statement is frequently made that cord blood at birth shows an upper normal limit of 5 to 10 nucleated erythrocytes for every hundred white blood corpuscles

EFFLUVIUM SEMINIS AND STERILITY

To the Editor—A patient tells me that his wife never retains the semen in the vagina after sexual intercourse but expels it. Immediately after intercourse she goes to the bath room and in a short time most if not all of the semen drips down and out of the vagina into the toilet. Could this be a cause of sterility or do you think enough semen remains in the vagina to cause fertilization? They have been married for three years and have no children. What treatment is recommended for this condition?

Captain, M C, A. U. S

ANSWER.—Effluvium seminis after intercourse occurs in about 80 per cent of all married women, the fertile as well as the involuntarily childless. This fact by itself suggests that such an outflow is not necessarily associated with impaired fertility. Under normal anatomic conditions some spermatozoa arrive in the endocervix, if not at the moment of ejaculation, a few minutes thereafter at the latest. There is little likelihood that these will escape. The majority of the spermatozoa remain in the vagina, where they are promptly attacked by the acid vaginal moisture. Their period of survival is short, and it is not a matter of importance whether they are retained or lost.

The first procedure should be a postcoital examination. The wife should be seen within two hours after intercourse, preferably at the midpoint of her menstrual cycle, and several drops of endocervical mucus should be examined microscopically. If living spermatozoa are found, obviously effluvium of the vaginal pool has not interfered with the mechanics of conception. If, on the other hand, spermatozoa are not present in the cervix, the cause of this abnormality should be sought The chances of cervical insemination will be increased if the wife, instead of arising and going immediately to the toilet, lies quietly for ten minutes on her back, perhaps with a pillow under her hips. Possible disorders to be investigated include premature ejaculation, hypospadias, urethral stricture in the husband and anteflexion or anteversion of the cervix If repetition of the postcoital examination still does not show spermatozoa in the endocervix after all such conditions have been ruled out or corrected, artificial insemination may be considered.

It should not be forgotten that there are many causes of infertility other than faults in the mechanism of cervical insemination and that the average sterile mating presents a combination of several causative factors Complete diagnostic study of both husband and wife is essential

EFFECT OF ALTITUDE ON HEART WORK

To the Editor:—Is the human heart called on to perform the same work at sea level as at an altitude of 8,500 feet under the same circumstances of rest, exercise and disease? Must the human heart increase its effort when climbing in a plane to high altitudes, from sea level to 8,500 feet? If this is so, would a man with heart disease be, in effect, putting his heart at rest by descending to a sea level area from a high altitude? Are dangerous consequences to be expected from a change of altitude for a person with heart disease?

G Aroaz Fraser, M D, Bogota, Colombia

ANSWER.—Since the pressure of oxygen in the inspired air is decreased at higher altitudes because of the decrease of atmosphere at points much elevated above sea level, there is a definite increase in the work of the heart needed to supply an adequate amount of oxygen to the tissues. This statement is true under the same circumstances of rest, exercise and disease—even climbing in a plane from sea level to 8,500 feet increases the work of the heart. In persons with heart disease, if this is relatively slight and myocardial and coronary reserve are reasonably good, harm does not result from such an ascent; few instances of serious consequence, even in those who have heart disease, have ever been reported as a result of airplane flights.

Descent to sea level from a high altitude does afford some rest for the heart: it was calculated by Barcroft and his associates in 1922 that at an altitude of 15,000 feet the heart works about 20 per cent harder to accomplish 20 per cent less work than at sea level (Barcroft, J., and others Observations on the Effect of High Altitude on the Physiological Process of the Human Body, Carried Out in the Peruvian Andes, Chiefly at Cerro de Pasco, *Philos. Trans. Roy. Soc.*, London, 1921-1923, Series B **211**:351-480).

MANAGEMENT OF CONVULSIONS IN THE NEWBORN

To the Editor—What are the relative value and suitable dosage of the following anticonvulsants for the newborn baby averaging 7 pounds (3 2 Kg): phenobarbital sodium, chloral hydrate, 50 per cent solution of magnesium sulfate, and morphine? What are the relative value and dosage for the newborn of the following respiratory stimulants: caffeine and sodium benzoate, nikethamide (25 per cent solution of pyridine beta-carboxylic acid diethylamide), metrazol, alpha-lobelin, carboxygen? Are there any other respiratory stimulants or anticonvulsants that are more reliable?

M.D., New York.

ANSWER.—In the management of convulsions in the newborn, anticonvulsant drugs are frequently neither necessary nor advisable. If the convulsions are due to an asphyxia, treatment should be directed primarily at relieving the cause of the asphyxia, which is often due to some mechanical obstruction. If the convulsions are due to a hypoglycemia, the use of intravenous or subcutaneous dextrose solution is a life saving measure. In those children in whom there is an increase in the intracerebral pressure as the result of intracerebral hemorrhage or edema, a lumbar puncture may stop the convulsions. In tetany of the newborn calcium salts parenterally or by stomach tube are indicated.

Anticonvulsant Drugs and Dosages

By Inhalation
- * Chloroform
- * Vinethene
- Ether

By Intravenous or Intramuscular Route
- * Barbiturates
  - Phenobarbital sodium
  - Sodium amytal
  - Pentobarbital sodium
  - Seconal sodium

  Dosage—⅛ to ½ grain (0.008 to 0 032 Gm) but usually ¼ grain (0 016 Gm), 0 33 cc of 5 per cent solution. When given intravenously, inject slowly, and when convulsions stop, give no more
- Paraldehyde 0 75 cc. (should not be given intramuscularly).
- Magnesium sulfate 2 to 5 cc. of the 10 per cent solution intramuscularly.
- * Recommended or preferred drugs.

By Rectal Route
- * Barbiturates
  - Phenobarbital
  - Amytal
  - Pentobarbital
  - Seconal

  ½ to ¾ grain (0 032 to 0 05 Gm).
- * Solution of tribromoethanol 60 to 100 mg. per kilogram
- * Evipal sodium 1 50 to 2 cc. of 10 per cent solution
- Chloral hydrate 3 to 5 grains (0 2 to 0 32 Gm.).
- Sodium bromide 3 to 5 grains (0.2 to 0 32 Gm).
- Ether in oil 10 cc of 50 per cent ether in olive oil
- * Recommended or preferred drugs

When, however, it is found desirable to use some anticonvulsant drug, the accompanying table indicates the dosages and route of administration. Barbiturates are the drugs of choice and should be given by injection or rectally.

Although a 50 per cent solution of magnesium sulfate may be used, it is definitely not the drug of choice, since its parenteral administration may result in depression of the respiration. For the same reason morphine is contraindicated in convulsions of the newborn. The only type of convulsions of the newborn in which morphine or its related alkaloids are indicated is those occurring in children born to women who are narcotic addicts In these children the convulsions are often a manifestation of the withdrawal of morphine and are best controlled by paregoric given in oral doses of 5 to 10 drops every fifteen minutes until the spasms subside. In very severe convulsions in the newborn it may sometimes be necessary to use a whiff of chloroform or vinethene for immediate control. These are preferable to ether because of their faster action

The dosages for the respiratory stimulants for the newborn are as follows:

Caffeine and sodium benzoate 0 5 to 1 cc. of an ampule containing 7½ grains (0 5 Gm) in 2 cc.

Nikethamide 0.5 to 0 75 cc of an ampule containing 25 per cent solution in 1.5 cc.

Metrazol 0.25 to 0 5 cc. of an ampule containing 1½ grains (0 2 Gm.) in 1 cc.

Alpha lobeline 1 cc of an ampule containing $\frac{1}{20}$ gram (0 0032 Gm.).

Camphor in oil 0.25 to 0 5 cc of an ampule containing 3 grains (0.2 Gm) in 1 cc.

Picrotoxin 0.25 cc. of an ampule containing $\frac{1}{20}$ gram (0 0032 Gm) in 1 cc.

Carbon dioxide 5 per cent and oxygen 95 per cent is supplied through a nasal mask and preferably through a resuscitator.

Since there is no definite proof that any of these respiratory stimulants are responsible for the initiation of breathing in the newborn child, it would be difficult to evaluate the relative efficacy of each or of any of the numerous similar products which are on the market. It should be borne in mind that convulsions may ensue from the use of metrazol or picrotoxin in some infants.

As previously stated, the best treatment of asphyxia is that aimed at clearing the respiratory passages. The proper and judicious use of a tracheal catheter is probably of greater value than any or all of the drugs which are discussed.

"FIBERGLAS" NOT CAUSE OF PNEUMONOCONIOSIS

To the Editor:—Compartments in the service ships are being lined with mats of "Fiberglas," presumably for insulating and sound proofing purposes. Several shipworkers have had severe persisting cough, sometimes lasting for many months, which they ascribe to the "Fiberglas" dust. Some men have physical signs of bronchitis, some do not. One man who had coughed for seven months—since beginning to work with the "Fiberglas"—has no definite physical signs of silicosis, and his x-ray film is normal except for a number of Ghon shadows. Is there not an industrial hazard of silicosis? No respirators or masks are issued.

Bernhard A. Fedde, M.D., Brooklyn.

ANSWER.—Unpublished animal experiments at the Saranac Laboratory have demonstrated that "Fiberglas" is not inhalable in appreciable quantities. After exposures of three years with the maximum atmospheric concentrations that could be maintained, the lungs of guinea pigs and white rats contained practically no fiber, and no scar tissue developed. The fiber used for insulation varies from 3 to 10 microns in diameter, which is too coarse to penetrate the lungs. A specially prepared fiber, 3 microns or less in diameter, was also excluded from the lungs apparently because it carries an electrostatic charge which causes it to adhere and mat on surfaces with which it comes in contact. Annual x-ray examinations of employees manufacturing this product have revealed no signs of pulmonary reaction. While Fiberglas is irritating to the skin and upper respiratory membranes, it does not cause pneumonoconiosis.

VARIATION OF BLOOD PICTURE IN VENOUS AND CAPILLARY BLOOD

To the Editor:—Is there any difference in the determination of hemoglobin percentage and the red cell count in blood obtained from the finger tip, the ear lobe or venous blood from the cubital vein after application of a tourniquet?

Abraham A. Brauer, M.D., East Chicago, Ind.

ANSWER.—There are no differences between samples obtained from the first two sites. Differences between these and venous blood are not of great magnitude and depend more on standardized technic than on the location. Blood from the ear lobe or the finger tip is usually mixed venous and capillary blood; therefore it would be slightly less venous than that from the cubital vein, but it would still be within the range of technical variation. The best procedure would be for the technician to make simultaneous determinations from the three sites and to determine the extent to which his personal technic would introduce an error.

VAGINAL DOUCHES

To the Editor:—What is the position of the leading authorities on the douching of the vagina in girls and unmarried women for the treatment of distressing odors arising from discharges in the vagina? Is it good practice to advise both young women and little girls to douche at home?

Raymond Lublin, M.D., East Hartford, Conn.

ANSWER.—J. P. Greenhill in his chapter on vaginal douches in "Office Gynecology" (ed. 3, Chicago, Year Book Publishers, Inc., 1943) says:

"There is no unity of opinion among either physicians or women concerning the value of vaginal douches. At one extreme one finds women who take a douche every day, except during menstruation, in the belief that it is a cleansing process equivalent to brushing the teeth. At the other extreme are women who never take a douche, not even after sexual intercourse. In between are women who take douches after coitus, after the menstrual flow is over and on special occasions. Those who douche use a variety of substances in the douche water, and physicians prescribe a large number of douche preparations."

"Are douches essential, and are there any types of douche medication which may be harmful?"

"I believe that women who have a normal qualitative and quantitative vaginal secretion should not take douches at all except perhaps after intercourse and at that time only to accomplish mechanical cleansing of the vagina."

L. R. Wharton in "Gynecology" (Philadelphia, W. B. Saunders Company, 1943) says:

"Many perfectly healthy women who have no leukorrhea use douches two or three times a week for the sake of cleanliness. This is perfectly reasonable as long as one administers the douche properly, uses the proper solutions and keeps the apparatus clean. The greatest dangers that attend such hygienic douching are the possibility of causing local irritation by using solutions that are strong or too hot and the risk of introducing infection, due to a contaminated douche apparatus."

The chief obstacle to the use of douches in young girls is an intact hymen. For an unmarried woman with a dilated hymen due to coitus, the use of vaginal menstrual plugs or other reason, there is no reason not to prescribe douches just as for married women, provided there is a valid indication such as a malodorous discharge. For little girls, however, satisfactory treatment can nearly always be carried out by a physician without the necessity of douches. In some cases the hymenal orifice must be widened, but there should be no moral reason against this. However, it is best to explain to the child's mother not only the intention of partially dilating the hymen but also the necessity for the procedure. Most of the public and many physicians are of the firm opinion that no attempt should be made to insert a finger or even an instrument through a virginal hymen, but there are times when this must be done both for diagnosis and for treatment. It is time that physicians educated the public to the fact that a dilated hymenal orifice is not necessarily a sign of lack of virginity.

NEGRI BODIES NOT FORMED BY RABIES VACCINE

To the Editor:—In our community we always have mad dog scares. It has been my observation that, even though the animal does not possess any symptoms of rabies, almost invariably when it is killed and the head sent to either the state laboratory or the Texas A. & M. College Laboratory a report of rabies is given. It does not appear rational that there can be this many rabid animals almost continuously. I should like to know if, after vaccination of animals for rabies, the peculiar inclusion or Negri bodies are found within the cytoplasm of the ganglion cells of the central nervous system.

Joseph Corrigan, M.D., Conroe, Texas.

ANSWER.—As far as known, Negri bodies do not develop in dogs vaccinated against rabies even if vaccines of active virus are used. It appears that Negri bodies are formed only by "street" strains of the rabic virus and not by virus that has been passed through animals in the laboratory. At present only fixed virus is used in making vaccines, that is, virus which has been passed intracerebrally many times through animals. It should be kept in mind that, in dogs, unrecognized rabies probably greatly exceeds the recorded incidence.

HYPERTRICHOSIS OF ARMS AND LEGS

To the Editor:—A neurosis is developing in a young woman because of hypertrichosis of the arms and the legs. Any successful treatment of the neurosis will require consideration of the hypertrichosis, with permanent epilation if possible. What is the most successful and practical method of permanent epilation, if any? Have the x-rays been used in this way? If so, has the method been successful, safe and practical? What is the most satisfactory method of temporary removal and bleaching? M.D., Indiana.

ANSWER.—Permanent epilation by means of x-rays is not safe and should not be attempted. The electric needle is safe and permanent but is time consuming and expensive, and, if not carefully done, it may be followed by disfiguring scars. Bleaching by means of a mixture of hydrogen peroxide and ammonia water may reduce somewhat the visibility of the hairs. If the patient can be induced to make use of an electric razor it will be found to be the simplest and most effective method of management.

TRANSFUSION OF WHOLE AND CITRATED BLOOD

To the Editor:—Immediately following or during a persistent hemorrhage is there any difference to be expected from the use of whole blood or citrated blood in transfusion? Will the two have the same value to the patient? Will the clotting of the patient's blood be materially affected either way? I assume that there is no defect in the patient's own clotting mechanism but that the blood loss is due to trauma such as would occur following an operation. M.D., New York.

ANSWER.—Unmodified and citrated blood are equally effective in the treatment of postoperative or traumatic bleeding. Assuming that there is no defect in the patient's clotting mechanism, neither sort of blood would produce an appreciable effect on the coagulability of the blood.

CLINICAL SIGNIFICANCE OF STAPHYLOCOCCI

WITH NATURAL OR ACQUIRED RESISTANCE TO THE SULFONAMIDES AND TO PENICILLIN

WESLEY W. SPINK, M.D.

MINNEAPOLIS

A problem of considerable importance in the chemotherapy of infectious diseases has been the development and dissemination of sulfonamide resistant strains of bacteria. Strains of micro-organisms within the different species known to be highly susceptible to the antibacterial action of the sulfonamides have acquired the characteristic of multiplying in the presence of high concentrations of the drugs. This acquired resistance appears to be a permanent property of these strains, and the resistant organisms are just as invasive as their sulfonamide sensitive progenitors. The mechanism whereby species of bacteria become relatively resistant to the sulfonamides is not completely understood, but it is related to the exposure of sensitive organisms to sublethal concentrations of the sulfonamides. Clinicians are rapidly becoming aware of the increasing incidence of gonorrhea in patients in whom the disease cannot be eradicated with intensive sulfonamide therapy. To a lesser extent this also applies to other bacterial infections such as those due to the pneumococcus and the hemolytic streptococcus. Fortunately, some strains of bacteria which develop resistance to the action of the sulfonamides may be highly susceptible to penicillin.

Our purpose in this report is to review briefly a group of investigations which have been carried out in this clinic with reference to the resistance of staphylococci to the action of the sulfonamides. More recently, further observations have been made pertaining to the problem of natural and acquired resistance of staphylococci to penicillin. These biologic phenomena may have a direct bearing on the success or failure of chemotherapy in staphylococcic sepsis. With more and more penicillin being made available for civilian use, increasing interest is being manifested in strains of staphylococci which are naturally resistant to the action of penicillin or acquire a resistance to the drug. An attempt has been made to correlate clinical results with strain resistance to the sulfonamides and, especially, to penicillin.

From the Division of Internal Medicine of the University of Minnesota Hospitals and Medical School.
The penicillin was provided by the Office of Scientific Research and Development from supplies assigned by the Committee on Medical Research for investigations recommended by the Committee on Chemotherapeutic and Other Agents of the National Research Council.
The investigations incorporated in this report have been supported by grants from the Graduate School of the University of Minnesota, the Committee on Scientific Research of the American Medical Association, the Charles P. De Laittre Research Fund, University of Minnesota Medical School and Sharp and Dohme, Inc.

SULFONAMIDE RESISTANT STAPHYLOCOCCI

It is generally agreed that penicillin is superior to any of the available sulfonamides in the therapy of staphylococcic infections. Nevertheless, the problem of penicillin resistant strains of staphylococci may be best approached by reviewing some of the investigations which have been made relative to the antistaphylococcic action of the sulfonamides. In determining the susceptibility of staphylococci to the sulfonamides, a standard in vitro test has been employed with a chemically defined medium; the preparation of the medium and the method of testing have been described elsewhere.[1] From these observations the following have been concluded: 1. Sulfathiazole inhibited the growth of coagulase positive strains of staphylococci more consistently and completely than sulfanilamide, sulfapyradine, sulfadiazine and, more recently, sulfamerazine. The action of sulfathiazole, of all the foregoing sulfonamides, was the least inhibited by para-aminobenzoic acid.[2] 2. Strains of pathogenic staphylococci may develop resistance in vivo to the antistaphylococcic action of sulfathiazole following the administration of the compound to patients with staphylococcic infections. Subsequently this observation was correlated with the clinical results of sulfonamide therapy.[3] During the past three years, sulfonamide resistant strains have been encountered with increasing frequency, particularly in patients having infections of the urinary tract. This was attributed to the widespread and often continuous use of the sulfonamides in the treatment of patients with this type of staphylococcic infection. In several instances there was a close correlation between the in vitro resistance of a strain to sulfathiazole and the success or failure of sulfonamide therapy. 3. In studying the mechanism whereby staphylococci became resistant to the sulfonamides, the observation of Landy and his associates[4] was confirmed in that resistant strains elaborated an inhibitory substance consistent with para-aminobenzoic acid or closely related to it.[5] This has been further confirmed by Housewright and Koser.[6]

4. Strains of pathogenic staphylococci which had acquired a high degree of resistance to sulfathiazole by either in vitro or in vivo methods remained just as invasive as the sensitive parent strains. This acquired sulfonamide resistance is apparently a permanent characteristic of the staphylococci, since in a period of two years following many subcultures the strains have not diminished in resistance.

PENICILLIN RESISTANT STAPHYLOCOCCI

In view of the foregoing experience with the sulfonamides, it appeared highly desirable to carry out a similar group of investigations with penicillin and a large number of coagulase positive strains of staphylococci isolated from patients. The information which we wished to obtain was Do strains of pathogenic staphylococci vary in their susceptibility to the in vitro action of penicillin? Is strain variation reflected in the results of therapy? Does the staphylococcus acquire a resistance to penicillin following in vitro and in vivo exposure of the organisms to the drug? If resistance may be acquired, are the resistant strains just as invasive as the sensitive parent strains, and is the resistance a permanently acquired characteristic? And, finally, may clinical failures with penicillin be correlated with the in vivo development of penicillin resistance?

In the first group of studies, 68 strains of coagulase positive staphylococci were isolated from patients none of whom had received penicillin. The in vitro sensitivity of each of these strains to penicillin was compared with their susceptibility to sodium sulfathiazole.[7] Included in these strains were 25 strains which were resistant to sulfathiazole. It was observed that 8 of the 68 strains, or 12 per cent, were relatively resistant to penicillin, requiring 0.4 to 0.8 unit of penicillin per cubic centimeter of culture medium before growth was inhibited. Many of the sulfonamide resistant strains proved to be quite susceptible to penicillin. In other words, there was no correlation between sulfonamide resistance and susceptibility of the organisms to the action of penicillin. Kirby,[8] who has also recorded the isolation of naturally resistant strains of staphylococci from patients, was able to extract a potent inactivator of penicillin from such strains but not from strains of staphylococci sensitive to penicillin. We have confirmed this observation of Kirby.

The preceding observations indicated that the mode of action of penicillin on staphylococci differed from that of the sulfonamides, and this is now generally accepted. Penicillin appears to inhibit the growth of sensitive organisms by interfering with the dividing bacterial cell or one that is about to divide.[9] The action of penicillin is assumed to be bacteriostatic and, under some conditions, bactericidal. Rantz and Kirby[10] reported that penicillin was bacteriolytic for staphylococci. Since the sulfonamides differ from penicillin in their mechanism of inhibiting growth of the staphylococci, it might be assumed that the combined use of a sulfonamide and penicillin would be desirable in the treatment of some patients with staphylococcic infections. However, experimental data as a basis for such a procedure are conflicting. Some investigators[11] have shown by in vitro methods that the bacteriostatic action for penicillin is greater in the presence of sulfonamide than with penicillin alone, but this is not in agreement with the reports of others.[12]

The studies were continued by adapting four coagulase positive strains of staphylococcus to grow in the presence of increasing concentrations of penicillin.[13] In this manner two strains developed a high degree of resistance to the antistaphylococcic action of penicillin. One strain, which required 0.04 unit of penicillin per cubic centimeter to inhibit growth before adaptation, required 80 units after a period of several weeks' exposure to penicillin. A second strain, originally inhibited by 0.06 unit, necessitated 120 units for complete inhibition of growth after adaptation. Both of these strains remained quite sensitive to sodium sulfathiazole. Two other strains, decidedly resistant to sodium sulfathiazole but sensitive to penicillin, were adapted to grow in penicillin, with the result that the strains manifested a resistance to both sodium sulfathiazole and to penicillin. This confirmed the results of others[14] that staphylococci may develop in vitro resistance to penicillin and offered further evidence that the mechanism of acquired sulfonamide resistance differed from penicillin resistance. Schnitzer and his group[15] have stated that there are three types of penicillin resistant staphylococci. The first type includes strains with natural resistance, the second embraces the strains which acquire resistance, and the third involves small colony variants (G forms) of a strain of Staphylococcus albus which exhibited a nonspecific form of penicillin resistance. Demerec[16] has presented evidence that the development of in vitro resistance of staphylococci to penicillin does not result from the action of penicillin on the organisms but originates through a selective process whereby nonresistant individuals are eliminated by the drug, and, through mutation, the more resistant cocci multiply.

We have also observed that organisms which developed resistance to penicillin by in vitro methods were killed in considerable numbers by human whole blood, whereas the sensitive parent strains and also sulfonamide resistant strains resisted this bactericidal action of blood. It is of interest that, although the penicillin resistant strains retained their ability to coagulate human plasma, they lacked the usual degree of resistance to the bactericidal action of blood exhibited uniformly by coagulase positive strains of staphylococci.[17] It has also been previously shown in this laboratory that the less invasive coagulase negative

strains of staphylococci were, with rare exceptions, killed in large numbers by human whole blood. This suggested, at least, that the metabolic activity of the penicillin resistant strains had undergone a change and the organisms had become less virulent. But this has little or no clinical significance, since organisms which have become resistant to penicillin in the human body are as resistant to the bactericidal action of human blood as the penicillin sensitive parent strains.

Several strains of staphylococci which had developed a high degree of resistance to the sulfonamides by in vitro adaptation have retained this resistance without diminution for almost three years. In other words, the acquisition of resistance to the sulfonamides by staphylococci appears to be a permanently acquired characteristic. It appeared at first that this also applied to staphylococci with acquired penicillin resistance, because the first few subcultures revealed that the organisms retained this insensitivity. However, further subcultures of four strains showed that the organisms had lost this acquired resistance. At the same time, these strains reverted to resisting the killing power of human whole blood to the same degree as the penicillin sensitive parent strains. Strains made resistant to both sulfathiazole and penicillin showed no decrease in sulfonamide resistance, even though the acquired pencillin resistance was lost. Further investigations in this laboratory have revealed that strains of staphylococci which have become resistant to penicillin in the human body following the administration of penicillin to patients develop a resistance which is probably permanent, and this in vivo strain resistance is associated with the production by the organisms of a potent inhibitor of penicillin activity.

The foregoing data on the sulfonamides and penicillin may be summarized as follows: Coagulase positive strains of staphylococci may be readily adapted to grow in the presence of high concentrations of the sulfonamides by laboratory methods as well as by exposing the organisms to the drugs in the human body. These sulfonamide resistant strains appear to be just as invasive as the parent strains, and sulfonamide resistance is apparently a permanently acquired characteristic. The development of sulfonamide resistance is quite likely related to the elaboration of a sulfonamide inhibitor which is para-aminobenzoic acid or closely related to it. Recently Sevag and Green [18] have taken exception to this concept and have concluded "that the development of resistance to sulfonamides is associated with the development of a sulfonamide resistant type of glucose metabolism." Confirmation of their work is highly desired and necessary. Strains of coagulase positive staphylococci may be less readily adapted to resist the action of penicillin than that of the sulfonamides. Strains highly resistant to the sulfonamides may also develop a considerable degree of resistance to penicillin. Strains of staphylococci naturally resistant to penicillin produce an inhibitor of penicillin activity. Such an inhibitor has not been obtained from sensitive strains. The development of resistance of staphylococci to penicillin by in vitro methods is only a temporary biologic phenomenon. Such strains rapidly lose this property in the absence of penicillin. An inhibitor of penicillin is not obtained from strains made resistant by in vitro methods. On the other hand, strains of staphylococci which have become resistant in vivo as a result of therapy with penicillin retain this resistance as a permanent characteristic, and these resistant strains produce a potent inhibitor of penicillin activity.

Bact. 48: 623 (Dec.) 1944.

CLINICAL CONSIDERATIONS

The crystallization of these and similar laboratory investigations with reference to an interpretation of clinical results is beset with many difficulties. However, an organism manifesting a high degree of susceptibility to penicillin in the test tube is usually sensitive to equivalent amounts of penicillin in the human body. In fact, a higher degree of bacterial destruction may be anticipated in the body, since, in addition to penicillin, there is the added factor of a natural or acquired immune mechanism. This correlation does not apply so uniformly to the sulfonamides because of the presence of factors present in the tissues and body fluids which inhibit the action of the sulfonamides. When the newer sulfonamide derivatives were introduced into medicine, more potent antistaphylococcic agents became available. And yet such compounds as sulfathiazole and sulfadiazine proved to be less satisfactory than anticipated. Among other deficiencies it appeared that strains of staphylococci developed an increased resistance to the sulfonamides and that these strains were being disseminated. Since penicillin is a superior agent in the treatment of practically all infections due to staphylococci, at the present time in this clinic sulfadiazine and sulfathiazole are being reserved principally for the treatment of some urinary tract infections in which sensitivity tests reveal that the growth of the offending strain of staphylococcus is inhibited by low concentrations of these compounds. Therapeutic failures have invariably attended the treatment of patients with sulfonamides where in vitro tests showed the staphylococci to be highly resistant to the sulfonamides. Sulfathiazole is also being employed simultaneously with penicillin for a selected group of patients with other types of staphylococcic infections.

Little data have been recorded in the literature pertaining to the clinical results with penicillin where staphylococci have manifested a natural or acquired in vitro resistance to penicillin. Bloomfield and his associates,[19] in a timely review of therapeutic failures encountered in their clinic, concluded that the development of organisms resistant to penicillin is probably of little importance but that there is very likely a correlation between initial in vitro strain sensitivity and the response to penicillin. Keyes,[20] in a discussion of the use of penicillin in ophthalmology, stated that the early treatment with inadequate concentrations of penicillin may result in the development of insensitive organisms. Under these circumstances intensive treatment with penicillin or the combined or alternate use of sulfonamides should be tried. In the treatment of chronic staphylococcic infections he suggests a preliminary in vitro test of sensitivity of the organisms. Anderson and his associates [21] have reported on the use of penicillin in the treatment of 40 cases of chronic osteomyelitis. In 5 cases there was no improvement, and in 4 of these failure to improve was considered as being due to the fact that the organisms became resistant to penicillin. In 19 of the patients the sensitivity of the organisms cultured from local lesions was tested before therapy, and then one or more weeks after therapy

4. Strains of pathogenic staphylococci which had acquired a high degree of resistance to sulfathiazole by either in vitro or in vivo methods remained just as invasive as the sensitive parent strains. This acquired sulfonamide resistance is apparently a permanent characteristic of the staphylococci, since in a period of two years following many subcultures the strains have not diminished in resistance.

PENICILLIN RESISTANT STAPHYLOCOCCI

In view of the foregoing experience with the sulfonamides, it appeared highly desirable to carry out a similar group of investigations with penicillin and a large number of coagulase positive strains of staphylococci isolated from patients. The information which we wished to obtain was Do strains of pathogenic staphylococci vary in their susceptibility to the in vitro action of penicillin? Is strain variation reflected in the results of therapy? Does the staphylococcus acquire a resistance to penicillin following in vitro and in vivo exposure of the organisms to the drug? If resistance may be acquired, are the resistant strains just as invasive as the sensitive parent strains, and is the resistance a permanently acquired characteristic? And, finally, may clinical failures with penicillin be correlated with the in vivo development of penicillin resistance?

In the first group of studies, 68 strains of coagulase positive staphylococci were isolated from patients none of whom had received penicillin. The in vitro sensitivity of each of these strains to penicillin was compared with their susceptibility to sodium sulfathiazole.[7] Included in these strains were 25 strains which were resistant to sulfathiazole. It was observed that 8 of the 68 strains, or 12 per cent, were relatively resistant to penicillin, requiring 0.4 to 0.8 unit of penicillin per cubic centimeter of culture medium before growth was inhibited. Many of the sulfonamide resistant strains proved to be quite susceptible to penicillin. In other words, there was no correlation between sulfonamide resistance and susceptibility of the organisms to the action of penicillin. Kirby,[8] who has also recorded the isolation of naturally resistant strains of staphylococci from patients, was able to extract a potent inactivator of penicillin from such strains but not from strains of staphylococci sensitive to penicillin. We have confirmed this observation of Kirby.

The preceding observations indicated that the mode of action of penicillin on staphylococci differed from that of the sulfonamides, and this is now generally accepted. Penicillin appears to inhibit the growth of sensitive organisms by interfering with the dividing bacterial cell or one that is about to divide.[9] The action of penicillin is assumed to be bacteriostatic and, under some conditions, bactericidal. Rantz and Kirby[10] reported that penicillin was bacteriolytic for staphylococci. Since the sulfonamides differ from penicillin in their mechanism of inhibiting growth of the staphylococci, it might be assumed that the combined use of a sulfonamide and penicillin would be desirable in the treatment of some patients with staphylococcic infections. However, experimental data as a basis for such a procedure are conflicting. Some investigators[11] have shown by in vitro methods that the bacteriostatic action for penicillin is greater in the presence of sulfonamide than with penicillin alone, but this is not in agreement with the reports of others.[12]

The studies were continued by adapting four coagulase positive strains of staphylococcus to grow in the presence of increasing concentrations of penicillin.[13] In this manner two strains developed a high degree of resistance to the antistaphylococcic action of penicillin. One strain, which required 0.04 unit of penicillin per cubic centimeter to inhibit growth before adaptation, required 80 units after a period of several weeks' exposure to penicillin. A second strain, originally inhibited by 0.06 unit, necessitated 120 units for complete inhibition of growth after adaptation. Both of these strains remained quite sensitive to sodium sulfathiazole. Two other strains, decidedly resistant to sodium sulfathiazole but sensitive to penicillin, were adapted to grow in penicillin, with the result that the strains manifested a resistance to both sodium sulfathiazole and to penicillin. This confirmed the results of others[14] that staphylococci may develop in vitro resistance to penicillin and offered further evidence that the mechanism of acquired sulfonamide resistance differed from penicillin resistance. Schnitzer and his group[15] have stated that there are three types of penicillin resistant staphylococci. The first type includes strains with natural resistance, the second embraces the strains which acquire resistance, and the third involves small colony variants (G forms) of a strain of Staphylococcus albus which exhibited a nonspecific form of penicillin resistance. Demerec[16] has presented evidence that the development of in vitro resistance of staphylococci to penicillin does not result from the action of penicillin on the organisms but originates through a selective process whereby nonresistant individuals are eliminated by the drug, and, through mutation, the more resistant cocci multiply.

We have also observed that organisms which developed resistance to penicillin by in vitro methods were killed in considerable numbers by human whole blood, whereas the sensitive parent strains and also sulfonamide resistant strains resisted this bactericidal action of blood. It is of interest that, although the penicillin resistant strains retained their ability to coagulate human plasma, they lacked the usual degree of resistance to the bactericidal action of blood exhibited uniformly by coagulase positive strains of staphylococci.[17] It has also been previously shown in this laboratory that the less invasive coagulase negative

On the other hand, strains of staphylococci which have become resistant in vivo as a result of therapy with penicillin retain this resistance as a permanent characteristic, and these resistant strains produce a potent inhibitor of penicillin activity.

Absence of Correlation Between Resistance and the Formation of Arylamine by Staphylococcus Aureus; Noninterference with the Utilization of Glucose as a Critical Factor in the Development of Resistance to Sulfonamides, J. Bact. **48**: 623 (Dec.) 1944.

CLINICAL CONSIDERATIONS

The crystallization of these and similar laboratory investigations with reference to an interpretation of clinical results is beset with many difficulties. However, an organism manifesting a high degree of susceptibility to penicillin in the test tube is usually sensitive to equivalent amounts of penicillin in the human body. In fact, a higher degree of bacterial destruction may be anticipated in the body, since, in addition to penicillin, there is the added factor of a natural or acquired immune mechanism. This correlation does not apply so uniformly to the sulfonamides because of the presence of factors present in the tissues and body fluids which inhibit the action of the sulfonamides. When the newer sulfonamide derivatives were introduced into medicine, more potent antistaphylococcic agents became available. And yet such compounds as sulfathiazole and sulfadiazine proved to be less satisfactory than anticipated. Among other deficiencies it appeared that strains of staphylococci developed an increased resistance to the sulfonamides and that these strains were being disseminated. Since penicillin is a superior agent in the treatment of practically all infections due to staphylococci, at the present time in this clinic sulfadiazine and sulfathiazole are being reserved principally for the treatment of some urinary tract infections in which sensitivity tests reveal that the growth of the offending strain of staphylococcus is inhibited by low concentrations of these compounds. Therapeutic failures have invariably attended the treatment of patients with sulfonamides where in vitro tests showed the staphylococci to be highly resistant to the sulfonamides. Sulfathiazole is also being employed simultaneously with penicillin for a selected group of patients with other types of staphylococcic infections.

Little data have been recorded in the literature pertaining to the clinical results with penicillin where staphylococci have manifested a natural or acquired in vitro resistance to penicillin. Bloomfield and his associates,[19] in a timely review of therapeutic failures encountered in their clinic, concluded that the development of organisms resistant to penicillin is probably of little importance but that there is very likely a correlation between initial in vitro strain sensitivity and the response to penicillin. Keyes,[20] in a discussion of the use of penicillin in ophthalmology, stated that the early treatment with inadequate concentrations of penicillin may result in the development of insensitive organisms. Under these circumstances intensive treatment with penicillin or the combined or alternate use of sulfonamides should be tried. In the treatment of chronic staphylococcic infections he suggests a preliminary in vitro test of sensitivity of the organisms. Anderson and his associates [21] have reported on the use of penicillin in the treatment of 40 cases of chronic osteomyelitis. In 5 cases there was no improvement, and in 4 of these failure to improve was considered as being due to the fact that the organisms became resistant to penicillin. In 19 of the patients the sensitivity of the organisms cultured from local lesions was tested before therapy, and then one or more weeks after therapy

organisms which persisted in the lesions were tested again. Five strains revealed an increase in resistance, and, in 2 of the cases, cultures made a year after the completion of therapy with penicillin showed the organisms to be still resistant to penicillin. There was no correlation between the development of resistance and the dose of penicillin administered to the patients.

At the University of Minnesota Hospitals, 69 patients with staphylococcic infections have received penicillin. Thirty-one of the patients had a bacteremia. A report summarizing the results of therapy will be presented elsewhere. Whenever possible, the in vitro sensitivity of the staphylococcus to penicillin was determined before and after therapy. Among the cases of bacteremia there were nine deaths, and there was no convincing evidence that a fatal issue was associated with the development of penicillin resistant strains of staphylococci. Of the 38 patients without bacteremia, in only 2 instances was there evidence that staphylococci with acquired resistance may have prevented complete eradication of the infection; but the evidence was not conclusive. One of these patients had chronic osteomyelitis with a draining sinus, and the second had a draining sinus which followed a nephrectomy for pyelonephritis and a perirenal abscess. In analyzing all of the cases treated there was no certainty that naturally resistant strains of organisms were the cause of a therapeutic failure. Failure to eradicate infections was due to two main causes: First, the use of inadequate amounts of penicillin, owing in several instances to a scarcity of the material. In the treatment of infections caused by naturally resistant organisms, this factor of inadequate dosage may be quite important. But the degree of natural resistance is relative. The sensitivity test as used in this laboratory has failed to reveal a strain of staphylococcus not previously exposed to penicillin that was not inhibited by 1 unit of penicillin per cubic centimeter of medium, and well over 100 strains have been tested. While this concentration of penicillin in the plasma is not readily attained in patients by the administration of even large doses of penicillin, we have observed that doses of penicillin calculated to give a concentration of 0.2 to 0.3 unit per cubic centimeter of plasma have rapidly sterilized the blood when the in vitro test showed that 0.8 to 1 unit of penicillin was necessary to inhibit growth. This discrepancy may possibly be explained by the fact that the additive effect of penicillin aided the immune factors of the host in overcoming infections. In the treatment of staphylococcic infections, and particularly bacteremia, it is desirable in many instances to maintain blood concentrations of 0.2 to 0.3 unit of penicillin per cubic centimeter, especially when the sensitivity of the organisms is not known. Rantz and Kirby [22] have found that during the continuous intravenous administration of penicillin 2,500 units of penicillin per hour resulted in a concentration of 0.05 unit per cubic centimeter in the plasma; 5,000 units per hour, 0.10 unit; 10,000 units per hour, 0.2 unit; and 20,000 units per hour, 0.4 unit. We have observed that the growth of the majority of strains of coagulase positive staphylococci is inhibited in the test tube by 0.2 unit of penicillin or less. In the treatment of severe staphylococcic bacteremia we have had reasonably satisfactory results during the initial stages of therapy when we have used 200,000 to 300,000 units over a period of twenty-four hours. This means that the plasma concentration of penicillin approximated 0.2 unit per cubic centimeter during this period. On the other hand, in many instances the blood stream has been rapidly cleared of organisms when one-half this dose has been used.

The second group of causes for failures in therapy with penicillin has been the persistence of foci such as a staphylococcic endocarditis and thrombophlebitis involving the larger veins of the lower extremities; and the presence of relatively avascular infected tissues which interfere with direct contact of penicillin with the bacteria such as occurs in bone infections and in some types of infections of soft tissues. Under these circumstances surgical eradication of the foci, whenever possible, is a necessary procedure.

COMMENT

Since penicillin is now the most potent chemotherapeutic agent available for staphylococcic infections, there are only limited indications for the use of the sulfonamides. Until more information is available, in this clinic selected cases with urinary tract infections due to staphylococci are being treated with sulfathiazole or sulfadiazine. Most of the cases are chosen on the basis that the organisms manifest in vitro sensitivity to the sulfonamides. Patients having infections due to organisms which are sulfonamide resistant do not usually respond to sulfonamide therapy. While it would appear desirable to employ sulfathiazole or sulfadiazine along with penicillin in the treatment of a severe staphylococcic infection when the organisms are naturally resistant to penicillin but susceptible to the sulfonamide, there is a paucity of clinical information along these lines. Lockwood and his group [23] apparently successfully combined sulfonamide therapy with penicillin in a case of severe staphylococcic bacteremia. During the past two years we have been determining the in vitro sensitivity of staphylococci isolated from patients with staphylococcic bacteremia to both sodium sulfathiazole and to penicillin in an attempt to resolve this problem. Thus far it would appear that such a combination is probably unnecessary in the vast majority of patients, provided adequate amounts of penicillin are used.

From our observations over a period of two years, and from those of others, it is becoming more manifest that the development of penicillin resistant staphylococci during therapy is not a major problem. However, such a biologic phenomenon may influence the outcome of treatment in an occasional patient. The development of resistance is very likely dependent on the exposure of the cocci to sublethal concentrations of penicillin. Therefore the aim of therapy should be to eradicate the largest number of organisms in the shortest period of time. This implies the use of adequate doses of penicillin, particularly in the treatment of severe infections, and the eradication of any relatively avascular foci by surgical means. Since occasional strains of staphylococci appear to develop a permanent resistance to penicillin, the dissemination of these strains may be associated with therapeutic failures. Thus far this does not appear to have much clinical significance.

SUMMARY

1. Sulfonamide resistant strains of coagulase positive staphylococci are being recovered with increasing frequency from patients. This resistance appears to be a permanently acquired characteristic, and the development of resistance is not associated with a diminution in virulence.

22. Rantz, L. A., and Kirby, W. M. M.: The Absorption and Excretion of Penicillin Following Continuous Intravenous and Subcutaneous Administration, J. Clin. Investigation 23: 789 (Sept.) 1944.

23. Lockwood, J. S.; White, W. L., and Murphy, F. D.: The Use of Penicillin in Surgical Infections, Ann. Surg. 120: 311 (Sept.) 1944.

2. Coagulase positive strains of staphylococci are occasionally encountered which possess a natural resistance to penicillin. While this biologic phenomenon may be conducive to therapeutic failures with penicillin, the resistance is relative and may be overcome with adequate doses of penicillin. For this reason it is recommended that adults having severe staphylococcic infections should receive a minimum of 200,000 units of penicillin each twenty-four hours during the initial stages of therapy.

3. Coagulase positive strains of staphylococci may acquire in vitro and in vivo resistance to penicillin. The resistance to penicillin which has been developed by in vitro methods is only a temporary characteristic of the organisms. Resistance acquired in vivo as a result of therapy with penicillin appears to be a more permanently acquired property of the bacteria. Thus far the development of such resistance appears to be a minor cause of failures with penicillin.

4. Since some strains of coagulase positive staphylococci may show a resistance to penicillin but pronounced sensitivity to sulfathiazole or to sulfadiazine, it would appear desirable to utilize a combination of penicillin and sulfonamide therapy. However, more clinical evidence is required before ascertaining the merit of such a procedure.

TRAUMATIC INJURIES OF THE RECTUM

PAUL C. BLAISDELL, M.D.
PASADENA, CALIF.

At a previous meeting of this section I[1] discussed the operative injury of the anal sphincter. The present topic is a sort of sequel and is also apropos to current emphasis on traumatic surgery. The intraperitoneal complications of rectal injuries and concomitant damage to neighboring organs such as the bladder have been primarily stressed heretofore and rather fully reported (as their seriousness deserves) and hence will not concern us here.

On the other hand there is little to be found concerning the perineal issues alone and particularly their own essential significance in relation to devastating and even fatal sequelae. I do not have in mind the occasional unfortuitous complications of surgery in general but consequences inexorably determined by the surgeon's deliberate plan of operation and under his responsible control. These considerations not only pertain to traumatic injuries but comprise basic proctologic principles which even in their more obvious connections with commoner rectal pathologic conditions are too frequently disregarded by the surgeon. Hence my present remarks are of actually much wider import than the restricted subject implies.

The perineal complications of rectal injuries spring primarily from the innate and persistent tendency of such wounds to be fistulous in character. Now no one has reduced to anything approaching precise terms the behavior of tissues in explanation of fistula formation; in a vague and uncritical assumption that we understand this, a degree of familiarity with conditions predicating fistula formation and the bare sequence of events have been confused with actual knowledge of cause and effect. Even the conditions and sequences themselves, although well established, fail of ample cognizance.

Let us first picture a penetrating wound from the perianal skin into the rectum (fig. 1). Certainly all would recognize this without equivocation as a fistulous wound even though it is difficult to explain precisely why; wounds in general are wont to heal if their fresh edges are in such close apposition; it is infected—yes, but even infected wounds do heal, and, conversely, a fistula inaugurated in measure by fecal contamination may fail to heal even when freed from this influence; as far as that is concerned, sinuses originate (and persist) entirely apart from any fecal soiling whatever. For the moment, however, the point is to visualize the indisputable basic concept of a fistulous wound for comparison with a lacerated wound, which is the most common pattern of traumatic rectal injury (fig. 1). Unfortunately, the key to its proclivities and management is too frequently sought, perhaps unwittingly, in analogies with lacerations elsewhere in the body, both more frequent and familiar, rather than in the unrecognized imagery of the penetrating wound. To come at once to the point, such traumatic lacerated wounds of the rectum should be thought of in terms of penetrating wounds which lack only variable amounts of circumferential wall and which certain eventualities, unless deliberately opposed, almost invariably tend to complete. Thus, axiomatically, the less a lacerated wound approximates the penetrating one—in other words, the fewer walls it has—the less likely its transition to a fistula; and the fewest walls a wound may have is one—a flat wound—hence the least likely to become fistulous.

Now all of this may sound too elementary, and indeed it may be common knowledge in the abstract; but, if so, at least the practical application as evidenced by the case reports betrays distortion and misconception. For example, the suturing of traumatic rectal wounds constitutes the most obvious, the most frequent and potentially the most serious violation of principle; and yet it is not only sanctioned but advised in printed word. Tempting but fallacious is the too prevalent concept that if sutures prove ineffective by virtue of wound infection nothing has been lost by the attempt. Fallacious, for it had been proved that healing is thereby delayed not moderately but far beyond that of wounds left wide open from the start. This time differential represents, in addition to the development and alleviation of confined infection, considerable tissue degeneration and sloughing. Such, however, is but the least disservice of suturing.

The consequences may be even more adverse than the stormy course of wound disruption, for apparent uneventful healing is too frequently the deceptive and vicious union of the more superficial parts only, with concomitant separation of the depths. By such "bridging," sutures have insidiously but effectively contributed the missing wall which we designated as the essential distinction between a lacerated and a penetrating wound, a lacerated wound and a fistula. The cure of such a fistula requires in essence the recreation of the original wound with healing by granulation—this time without benefit of suture.

But mismanagement by the use of sutures may have a graver conclusion than either explosive wound disruption or unvisioned fistulas compelling reoperation. Here I refer to the formation of fistulas either totally incurable or those necessitating at best far greater mutilation for cure than simple recreation of the original wound. There is intimation of such fistulas in the literature but little as to their pathogenesis or prevention or indeed as to just why they are incurable. One thinks

Read before the Section on Gastro-Enterology and Proctology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

1 Blaisdell, Paul C.: Operative Injury to the Anal Sphincter, J. A. M. A. 112:614 (Feb. 18) 1939.

of the extent and relationships of a chronic fistula as being defined and limited by the pattern of the antecedent wound, of which the fistula is the direct residue. But as few traumatic wounds are in themselves incurable, whence then fistulas which transcend

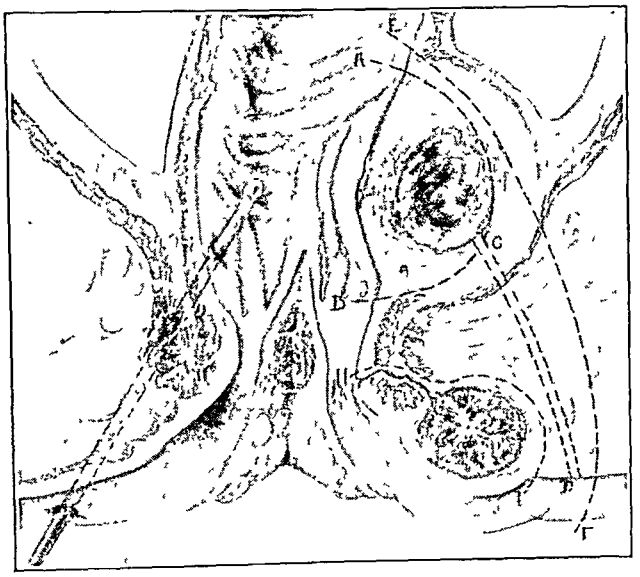

Fig. 1.—Composite drawing, illustrating several pathologic lesions: penetrating instrument and wound on the left, lacerated traumatic wound in the center with damage to the sphincter ani and perirectal abscess, right upper, such as occurred in case 1, following injury and suture of the rectal wall. Such an abscess, if taken early, should be curable by saucerizing within the arc of broken line *A B*. If, on the other hand, spontaneous pointing to the skin is awaited, or if evacuative incision is made through the perianal skin as represented by line *C-D*, as done in case 1, saucerization of the large arc *E-F* becomes necessary. This means not only a dissection of far greater magnitude but also inclusion within its scope of the whole sphincter mechanism. Perianal abscess, right lower, of daily encounter, in contrast to the rare ones of truly rectal origin, commonly misnamed "rectal" abscesses (and fistulas). Adequate saucerization following perianal evacuation, as indicated by broken line *H I*, rarely encompasses critical amounts of sphincter, again in contrast to the perirectal. This lesion is illustrated only for comparison and avoidance of possible confusion

in both extent and complexity their own inceptive wounds? And just where and how does the attribute of incurability appear from the nowhere and affix itself? The unfolding answers spring from the fact that, while wounds may resolve directly and imperceptibly into chronic fistulas, acute and fulminating abscesses are a frequent intermediary stage between either a closed or a bridged wound and the final chronic fistula. This extension of pus under pressure may expand many fold the limits of the original injury and complicate its relationships, especially by reason of delays in diagnosis and procrastination of treatment which invariably attend abscesses in this area. In the superimposed disasters of preventable abscesses, then, are the inexorable and hardy seeds of the problem fistula. The first case report well illustrates the train of events attendant on suture of the lacerated rectal wall with the resultant abscess acquiring such relationships to the sacrum as to make it virtually inoperable (figs. 1, 3, 4 and 6).

What does all of this mean then—that traumatic wounds had best be idly neglected? To the contrary, aggressively active measures are usually necessary to counteract a unique local factor which of itself subserves the same treacherous union of superficial wound edges as established by sutures. This factor resides in a sort of collapsed status of tissues in the area, less readily described by word than by comparison in a way to the closed position of an accordeon, and is dominated both by the anal sphincter and by the natural apposition of buttocks and thighs. These influences must be anticipated by the conversion of wounds to as nearly as possible flat or "saucerized" forms, if need be through sacrifice of normal tissue. Such requirement may be moderated somewhat by persistent postoperative manual separation of the wound edges and/or by extended gauze packing, their necessity increasing in direct proportion to operative conservatism. The detriments of tissue loss are obvious; but on the other hand adequate manipulations and repacking of the wound are painful ordeals for the patient, requiring anesthetics and extra hospitalization so that even short of their absolute limits of effectiveness such measures approach the unpractical. The danger of incontinence by the prolonged separation of muscle ends through continued packing must be mentioned. The proper balance between tissue sacrifice and postoperative intervention—to gain the most for the least—is exclusively in the realm of individual experience, but I emphasize that in both particulars the occasional surgeon fails far on the side of insufficiency.

There are not only reasonable and relative limits to these complementary devices in assuring sound healing but there are absolute limits, which in summation define the real meaning of incurability. The restrictions to saucerization in the ischiorectal fossa are imposed by its walls, viz. the ischial tuberosity laterally, the urogenital diaphragm anteriorly and the anal canal medially (fig. 2). It is to be noted in contrast that the posterior wall is not as restrictive; being composed largely of fat, it can be generously removed. Furthermore, the slope of the pelvic floor is such that the attachment posteriorly is at about the same level as the apex of the fossa. This means that the latter, even to its uppermost point, may be well reached with at least a gutter carried posteriorly alongside the coccyx

Fig. 2.—Anatomic structures having bearing on saucerization of wounds in the ischiorectal fossa. Restrictions are imposed by the ischial tuberosity laterally, the urogenital diaphragm anteriorly and the anal canal medially. The posterior wall, on the other hand, can be generously saucerized. Furthermore the coccyx is at about the level of the apex of the fossa, owing to the hammock shape of the levator, which relationship also facilitates saucerization carried out posteriorly. Not only are these facts pertinent to the intelligent management of traumatic injuries but they are basic in the everyday treatment of spontaneous fistulas.

Deeper in the pelvis its bony walls impose obvious and impervious limits to saucerization (case report 1 and figs. 3, 4 and 6).

INJURY TO THE ANAL SPHINCTER

How does injury to the anal sphincter affect the issues? By no amount of sophistry can it alter or negate the principles established. The severed ends are but part and parcel of a wound which has innate potentialities for harm, and any compromise of management in their behalf either lacks cognizance of these dangers or else fears that suture alone assures continence and that all other contingencies are, or should be, subordinate.

To answer this in entirety would be but repetitious, except for dispelling the misconception of muscle suture as the sole safeguard against incontinence. The mind's eye, reverting to terms of probably more familiar experience, pictures the severed muscle ends behaving as those of long muscles which retract apart even to considerable distance. Such are not the particulars here, where both constrictive and splinting forces and constraints, which I cannot here pause to analyze, incline to maintain coaptation of the severed ends. This is constantly verifiable in fistulectomies both by direct observation and by clinical result, these controls being indeed so effective that the site of severance, particularly,

Fig. 3.—Problem fistula in case 1, either incurable or at best responsive only to excessively mutilative surgery. Represents the residue of an abscess following traumatic injury to the rectum which was treated as described in text and illustrated in figure 4. The main body of the fistula, found later to have extremely firm walls a half inch thick, lies on the hollow of the sacrum. At the extreme left is the barium filled rectum, while between can be seen catheter entering tract of previous perianal incision of the postoperative abscess, now communicating with both the rectum and the main body of the fistula.

must be watched for bridging. That there is of course a limit to this reserve goes without saying. Suturing only the ends of a severed sphincter (fig. 5 and case 2) is a furtive synthesis of half-truths, combining a half-hearted open wound and recollected pictures of plastic repair. While not impossible of result by the expert, it bespeaks more likely a credulous naïveté which has stumbled onto a hard way of doing things when even the easier exceeded the surgeon's capability. Union of the *ends is the most facile contribution toward bridging*, which immediately implies (1) more radical treatment and expert management of the rest of the wound to prevent it too resolving to a fistula and (2) later severance of the union on the principle of a two stage fistulectomy. And why sutures in the classic repair of the incontinent sphincter if so ill advised in its immediate restoration? Too briefly for all the facts: (1) In the one case muscle recovery has reached equilibrium while in the other an advanced degree of improvement is in prospect and (2) the surgically created wound is controllable (*a*) in extent and (*b*) in site wholly outside of, and separated from, the anus. These admit of a more tractable pattern of nonfistulous character holding brighter prospects of sound healing and, at the worst, disruption to the status quo. Even so, this operation in such a soiled field is a compromise with the ideal, as

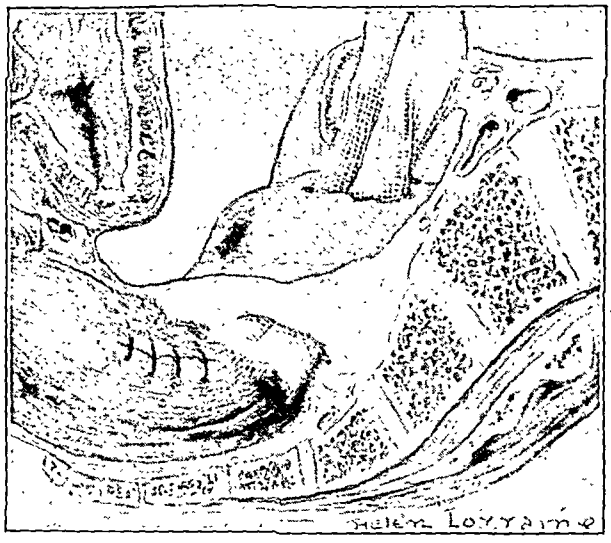

Fig. 4.—Method of treatment by surgeon in case 1. The important point is suture of the traumatic laceration of the rectum, which I hold to have been inadvisable. Drain carried from rectum through rent in peritoneum and up through abdominal wall. Several weeks later a retrorectal abscess formed which was opened through perianal skin (fig. 1), resulting in condition shown by x-ray in figure 3; such incision also is objectionable for reasons given in text and illustrated in figure 1.

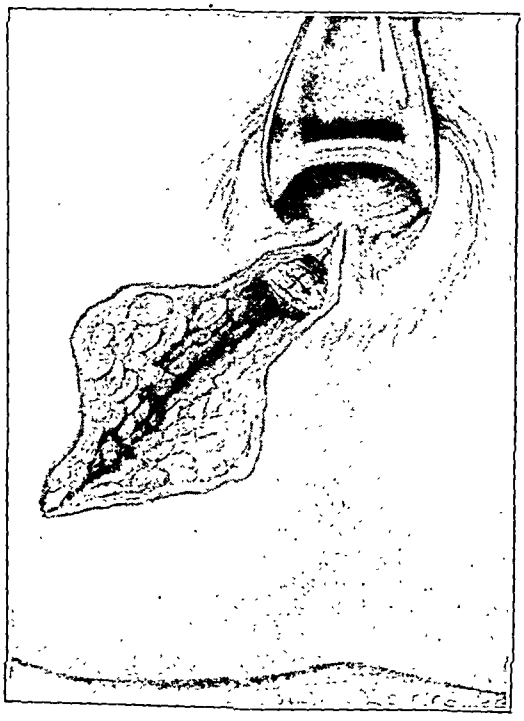

Fig. 5.—Treatment by surgeon in case 2. Only the severed sphincter ends were sutured, leaving the rest of the wound untouched. If the sutures slough, they serve no object; if not, a fistula of the whole wound is almost inevitable. If in addition the wound had been adequately saucerized, the sphincter possibly could have been severed later if the sutures held—on the principle of a two stage fistulectomy.

results compiled and reported by us elsewhere prove;[2] it is for this reason that in previous papers on elective

2. Blaisdell, Paul C.: Repair of the Incontinent Sphincter Ani, Surg., Gynec. & Obst. **70**: 692, 1940. Blaisdell, Paul C.: Repair of the Incontinent Sphincter Ani, ibid. **75**: 634, 1942.

repair I included suggestions of a vaginal approach more wholly consonant with logical principle.

The traumatically injured sphincter should be simply left alone, thereby taking full advantage of its own capacity of spontaneous recovery; if later this should prove wanting, circumstances for controlled intervention would then be far more propitious, safe and with wider choice of reparative procedure.

TEMPORARY COLOSTOMY

The establishment of a temporary colostomy in the treatment of injuries has been suggested, and, it seems to me, without critical analysis commensurate to such circuitous and radical surgery. Certainly a colostomy is not a preventive of a fistula because of the time lag of attributable effect—unless perchance one prepares the rectum by this means for an accident to happen some months later. The advocacy of colostomy has possibly evolved from the careless translation of special indication into more general terms—for example, from a

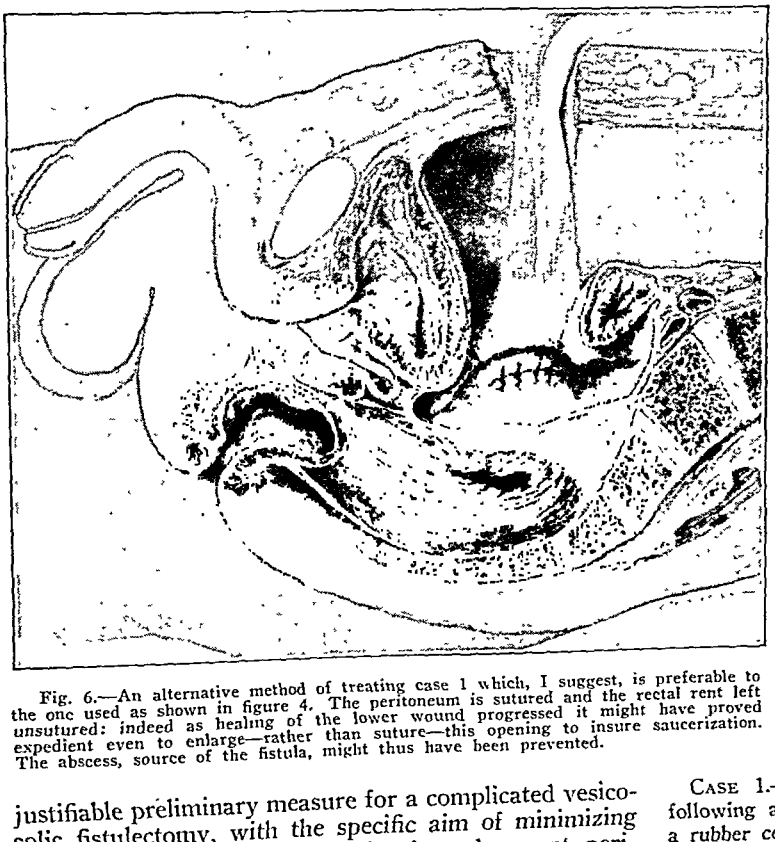

Fig. 6.—An alternative method of treating case 1 which, I suggest, is preferable to the one used as shown in figure 4. The peritoneum is sutured and the rectal rent left unsutured: indeed as healing of the lower wound progressed it might have proved expedient even to enlarge—rather than suture—this opening to insure saucerization. The abscess, source of the fistula, might thus have been prevented.

justifiable preliminary measure for a complicated vesicocolic fistulectomy, with the specific aim of minimizing the infective danger inherent in the subsequent peritoneal approach. Such an aim is entirely extraneous to any perineal issue, where, as we have seen, the sole obstacle to sound healing is restriction of adequate saucerization. I have encountered no evidence to establish that diversion of the fecal stream is a counter equivalent to such limitation—a point susceptible to experimental analysis which should have preceded clinical application. And there is considerable evidence to the contrary, such as in the behavior of recurrent pilonidal sinuses; for here, likewise, unsound healing is due far above all else to faulty wound architecture (shown by the fact that the recurrence rate is twenty times greater in sutured than in open wounds [3]) and yet devoid of any fecal stream influence, not belatedly effected either, as in the case of colostomy for wounds under discussion, but absent from the very inception.

There are objectionable possibilities in a temporary colostomy from a false sense of security induced. Indeed the test and criterion of management is the behavior and progress of the wound under what are to be its permanent environments.

TREATMENT OF THE INTERMEDIARY ABSCESS

If and when an abscess has been allowed to form (case 1), does there still exist any choice of management or should incision invariably be made perianally as well-nigh universally advised? The time element holds the key to the situation not only in minimizing both the progressive extent and the cumulatively complex relations outlined but also in offering any choice as to locus of incision. (By such choice I do not refer to direct incisional damage to the sphincter, although in a series of cases of incontinence that I compiled an incredible proportion were the result of simple incision of perianal abscesses.[4]) It must be admitted that procrastination usually settles all issues by unimpeded pointing of the abscess, but this does not prove that something better is impossible. The significance of the incisional site stems from the fact that the course of any incision becomes itself an integral part of the residual fistula, so that to this extent the relationships of the latter are determinable. With an abscess of intrarectal origin this in itself may make the whole difference as to whether the entire sphincter mechanism becomes involved or spared in the subsequent fistulectomy, with vital bearing on continence. Figure 1 portrays the theoretical background of this principle, as case 1 establishes the pragmatic and sober actuality.

This must not be construed of course as advice for the incision of the common perianal abscess of anal as distinguished from rectal origin, whose arc is so largely determined by embryonic anal ducts as rarely to include critical amounts of muscle, as also illustrated.[5]

REPORT OF CASES

The following are 4 consecutive cases of traumatic injury, with 3 illustrating points of mismanagement:

CASE 1.—A youth aged 18 entered the hospital directly following an accident in the mountains. Sliding downhill on a rubber coat he had collided with a sled, the steel runner of which penetrated upward through his rectum. Pronounced rigidity of the abdomen was the essential indication for immediate laparotomy by his attending surgeon. Through a midline incision exploration disclosed a rent in the pelvic peritoneum close to the iliac vein, and a small piece of raincoat near this opening was removed. The hole in the rectum was sutured, the pelvis cleaned, a drain carried to the rectum through the peritoneal defect and the abdomen closed around the drain (fig. 4). The latter was removed gradually over a period of days as drainage ceased.

Three months later the patient was readmitted because of septic fever of unstated duration and a large retrorectal abscess evacuated by a perianal incision lateral to the rectum (fig. 1) and the original traumatic tear of the rectum which had failed to heal was resutured. Coincident with healing of the perianal

3. In a compilation of over 4,000 cases of pilonidal sinuses submitted by members of the American Proctological Society, Kleckner found recurrence to be twenty times more in closed wounds than in those left wide open. This proves that recurrence is a matter of wound architecture and not of incomplete removal.

incision septic fever gradually returned, at which time the patient was referred to me. An x-ray film taken at this time is shown in figure 3.

Under gas anesthesia a belated attempt was made to saucerize the complicated fistula, leaving until later the problem of its encirclement of the whole sphincter mechanism. The patient was in good condition on leaving the table but within a few minutes became suddenly cyanotic, with labored breathing, and died within a few minutes before I reached his room. A postmortem was performed by Dr. Allvyn Foord, who ascribed death to massive collapse of the left lung. The abscess cavity in the hollow of the sacrum was found to have a wall of dense and extremely hard fibrous tissue 1 to 2 cm. in thickness, and only by sharp dissection with a heavy knife could it be stripped from the underlying bone. A far more radical operation than I had attempted would have been necessary for cure, if even possible.

Suture of the rectum was an invitation to a retrorectal abscess impossible of saucerization through the abdomen; inevitable sloughing of the sutures converted the abscess to a blind fistula. Resuture of the rectum across an abscess cavity is and was pointless, and perianal incision vastly complicated any possible cure of fistula, as explained in figure 1; instead, intrarectal saucerization should have been attempted. (See also figure 6.)

CASE 2.—A boy aged 10 years entered the hospital several hours following an impalement injury of the rectum suffered by falling on a picket fence. He was assigned to a general surgery service, where, in the absence of signs or symptoms of peritoneal encroachment, the lacerated sphincter ends were united by interrupted sutures; the remainder of the wound was simply left alone (fig. 5). After a period of several months the patient was referred to the rectal service because the wound continued to drain. On examination under anesthesia a deep fistula was found to occupy the entire original wound, necessitating fistulectomy by its recreation and saucerization, allowing it then to heal from the bottom by granulation. There was no residual muscle weakness.

This patient was forced to repeat surgery and weeks of convalescence because of mismanagement. Simply leaving the wound open was not sufficient to preclude fistula formation, additional saucerization being indicated. Suture of the muscle increased the likelihood of a fistula and served no useful purpose.

CASE 3.—A man aged 30 suffered an impalement injury of the rectum in an automobile accident, the details of which were not remembered by the patient. He was removed to a hospital near the scene and the whole wound closed with interrupted sutures, after which the patient was sent to me. After several days the wound broke down so badly that reoperation became immediately necessary; all sutures were removed and saucerization, which should have been carried out at the original operation, was now established.

If sutures hold, abscesses or fistulas and reoperation usually result as illustrated in cases 1 and 2; if ineffective, as here, they are also worse than useless, occasioning at best unnecessary surgery and delayed convalescence.

CASE 4.—A man aged 30 was thrown from a skidding motorcycle. He was assigned to the orthopedic service, where it was determined that he had suffered a broken humerus, femur and pelvis; I was consulted about a large gaping wound of the perineum entering the rectum. The patient was complaining of abdominal pain, but no rigidity was determinable. Immediate examination of the wound was carried out under anesthesia, and extension through the peritoneum was definitely ruled out. Even though it was already a large wound, much tissue was further sacrificed to obtain certain saucerization; this was particularly necessary because the other injuries would interfere with continued postoperative manipulation. Within a few days granulations made the wound quite insensitive and it required almost no care. The sphincter, although more than halfway severed by injury, healed without any loss of control.

Here is demonstration of conformity to logical principle.

LESIONS OF THE MUSCULOTENDINOUS CUFF OF THE SHOULDER

2. DIFFERENTIAL DIAGNOSIS OF RUPTURE

HARRISON L. McLAUGHLIN, M.D.
NEW YORK

The most adequate present guide to the diagnosis of rupture of the short rotator cuff of the shoulder is outlined and described in detail by the late Dr. E. A. Codman in his classic text "The Shoulder." [1] In considering the diagnostic aspects of rupture he frankly admitted that he never had had the opportunity to study a fresh case. He then went on to postulate eighteen conditions which he thought ought to be fulfilled before a positive diagnosis of early rupture should be made. His clinical syndrome was a rather exacting one which, in spite of its hypothetical nature, came surprisingly close to the mark. However, since the publication of his book a considerable number of proved ruptures, both early and late, have been studied by the Fracture Service of the Presbyterian Hospital in New York and certain modifications of and additions to this syndrome seem indicated.

The requirements for diagnosis of a cuff tear differ little if any from those of a tear in any other tendon or tendon group. They include:

1. A detailed history characterized by compatible subjective symptoms.
2. Demonstration of absent or deranged function in the structure involved.
3. Supportive evidence in the form of local signs compatible with damage to the structure involved.
4. Elimination of other conditions requiring differentiation.

HISTORY AND SYMPTOMS

Codman stipulated that the patient be a laborer past 40. Sixty proved ruptures form the basis of this report. Eleven were under 40. Five were under 30. Nineteen were in women, most of whom could not be classed as true laborers. It is evident that, while most ruptures occur in well used shoulders past middle age, the incidence of the lesion is by no means restricted to this age and group. Codman's statement might well be modified to say that the cuff in any laborer past 40 is sufficiently scarred and degenerated by repeated minor traumas and attrition that it ruptures with relative ease.

He stipulated that the history include an adequate trauma, usually a fall. If by this he meant trauma adequate to rupture a weak and degenerated tendon his hypothesis has been corroborated. Almost but not

From the Fracture Service of the Presbyterian Hospital in New York, and the Department of Surgery, Columbia University College of Physicians and Surgeons.

1. Codman, E. A.: *The Shoulder: Rupture of the Supraspinatus Tendon and Other Lesions In or About the Subacromial Bursa*, Boston, privately printed, 1934.

all patients date the onset or aggravation of symptoms from an injury of some sort. Few such injuries are serious in the ordinary sense of the word and many are minor enough so that they fittingly might be called inadequate. At times the most detailed history fails to uncover any trauma at all. An interesting characteristic of the pathologic condition found in the latter group is the presence of extensive fibrillation and degeneration of the tendon substance at the point of rupture not unlike that occasionally encountered in ruptures of middle aged achilles or quadriceps tendons. It seems reasonably certain that extensive degeneration at times so weakens the tendon substance that it may rupture without significant cause.

The rupture, whether spontaneous or the result of trauma, is accompanied by a sudden sharp pain in the shoulder. The patient often describes a sensation of something snapping or giving way. From this time on the history and symptoms generally follow a fairly consistent pattern. The primary pain is momentary and usually passes off, only to recur within a few hours. The quiescent period apparently represents the time necessary for the torn tissues to become swollen and inflamed so that their easy passage under the acromion and coracoacromial ligament no longer is possible. Once it is over, pain and spasm are continuous, aggravated by motion of the arm and especially those motions causing the torn portion to brush against the overlying bone or ligament. For the first few days the pain progressively increases in severity, reaches a peak and then gradually subsides. In many cases it subsides completely. In most cases it eventually reaches a level of severity at which it remains more or less constant and at which it may or may not result in sufficient disability to warrant radical therapy.

A definite diagnosis usually is impossible in the presence of acute pain which precludes adequate functional evaluation of the various muscular and ligamentous components of the shoulder. It is considered that no definite diagnosis, prognosis or radical treatment is warranted during the stage of acute pain. This is in direct variance with Codman's plea that such ruptures be diagnosed and repaired at an early date. He made this plea in the hope that early repair would be easier to do and might be followed by better and more speedy recovery. The following reasons substantiate the conviction that early repair is not warranted in the average case:

1. Early repair has been no easier to accomplish than late.

2. The results of early and late repair have been identical both for time and for completeness of recovery in comparable cases.

3. The symptoms in a large percentage of cases showing a clearcut clinical picture of rupture subside spontaneously under conservative therapy to such an extent that repair never need be done.

4. The rupture almost invariably takes place through a degenerated portion of the tendon. As a result, speedy and efficient union of the repair can be expected only after the degenerated edges of the tear are excised back to healthy tendon tissue. The rupture therefore is the equivalent of an old lesion as soon as it occurs, and whether operated on early or late excision and revision of its periphery is equally necessary.

The acutely painful stage usually commences to subside a week or so after the onset. When this occurs pain is replaced by actual weakness or inability in elevation of the arm as the predominant subjective complaint in the larger tears, and by minor derangements of function characterized by acute catches of pain in certain positions in the lesser lesions. A constant ache referred to the region of the deltoid insertion frequently persists in addition to the other symptoms. Usually at least two and not more than four weeks after the onset the painful symptoms are found to have subsided sufficiently so that a detailed functional examination is possible.

DEMONSTRATION OF ABSENT OR DERANGED FUNCTION

The function of the musculotendinous cuff is intricate and difficult to comprehend except on a basis of living anatomy. Its power of rotation is obvious. Cases with deltoid paralysis have indicated that abductor power, although present, is weak and inefficient when it acts alone. Codman has given a comprehensive description of its anatomy and physiology and emphasized its importance as a stabilizer of the glenohumeral fulcrum during abduction of the arm. Inman, Saunders and Abbott [2] emphasized and evaluated the relative importance of the various muscles with respect to their place in maintaining the muscle force couple of the shoulder mechanism. A retrospective study of a considerable number of cases with proved ruptures involving various segments of the cuff, and a correlation of the operative findings with detailed preoperative functional evaluations, have resulted in some additional useful observations.

The musculotendinous cuff consists mainly of the four intrinsic muscles of the shoulder whose origins arise from divergent points on the scapula and whose tendinous portions converge and fuse to form a continuous envelop enclosing the anterior, superior and posterior aspects of the humeral head and to insert into the bone at the region of its anatomic neck and tuberosities. The subscapularis portion of this common insertion attaches to the lesser tuberosity, the supraspinatus, infraspinatus and teres minor portions respectively to the anterior, middle and posterior facets of the greater tuberosity. The subscapularis is joined to the suprasinatus by an aponeurosis through which the fibers of the two tendons decussate.

It is a widely accepted belief that supraspinatus function constitutes an essential factor in the initiation and maintenance of abduction against gravity. Operative findings have proved this belief to be unfounded. Almost if not all patients with complete rupture of the supraspinatus alone have been able to initiate and maintain abduction of the extremity prior to repair. Larger tears involving more than one whole tendon have been found to retain these two functions in certain planes of humeral rotation and lose them in others. Complete avulsions of all the cuff insertion have shown a complete absence of power to initiate or maintain elevation in every plane of humeral rotation. Therefore it seems certain that although function of the cuff unit is essential to the initiation, performance and maintenance of elevation, that of the supraspinatus or any other individual member is not. It has been apparent that small ruptures such as those involving the supraspinatus alone are compensated for, when necessary, by the remaining intact attachments on either side, in

2. Inman, V. T., Saunders, J. B. deC. M., and Abbott, L. C.: Observations on the Function of the Shoulder Joint, J. Bone & Joint Surg. 26: 1-30 (Jan.) 1944.

the same way that intact vastus expansions compensate for the function lost with certain undisplaced patellar fractures.

The cuff, irrespective of the individual tendons involved, is divisible into anterior, superior and posterior segments as it embraces the humeral head (fig. 1). The anterior and posterior segments exert a rotary force. Their lower components exert what Inman, Saunders and Abbott have aptly termed a depresser force on the humeral head, although clinical findings do not entirely substantiate their estimate of the importance of this force in the act of elevating the arm. All three pull the humeral head against the glenoid. The superior segment has an additional mechanical advantage such that it exerts an abduction force on the humerus, acts as a depresser up to 90 degrees and past this point helps to suspend the humeral head against gravity. The particular tendon or tendons making up this superior segment depend on the rotational position of the humerus. In external rotation it is made up of the subscapularis and supraspinatus, in neutral by the supraspinatus and the anterior portion of the infraspinatus and in internal rotation by the infraspinatus and at times the teres minor (fig. 1). Operative findings correlated with preoperative functional defects have demonstrated clearly that the function of the tendons making up the superior segment in any given position of humeral rotation is the essential factor in both initiation and maintenance of abduction and that the function of the individual intrinsic muscles is interchangeable in this respect, depending on the position of the humerus and the plane of motion.

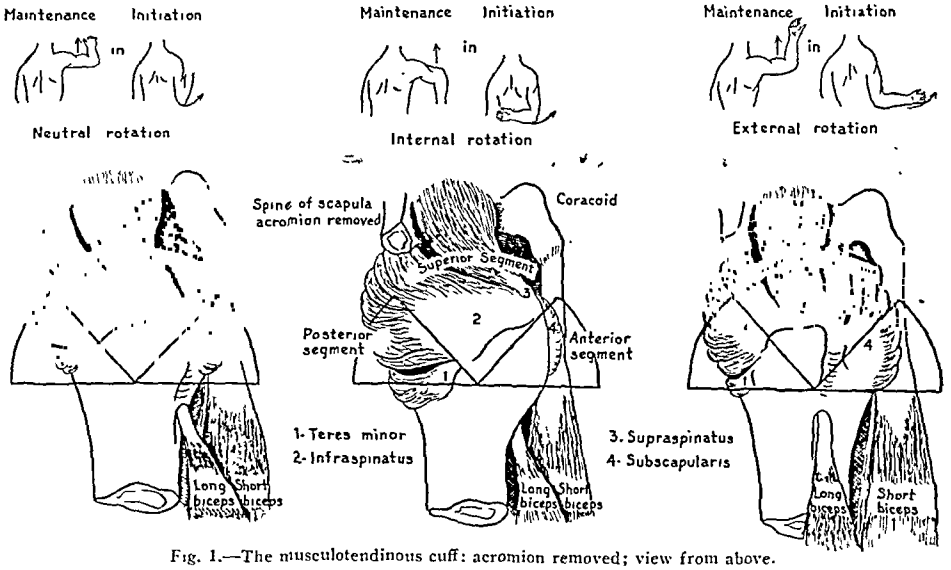

Fig. 1.—The musculotendinous cuff: acromion removed; view from above.

Knowledge of this fact makes possible an adequate functional evaluation, not only of the cuff as a whole, but also of its individual components. In the routine examination of shoulders it is considered essential that initiation and maintenance of abduction be tested in all planes of humeral rotation before deciding that the intrinsic muscle cuff is functionally intact. When a certain tendon is suspected of rupture the humerus is rotated until the suspicious area is brought into the position of greatest functional demand, i. e., brought to occupy a position in the superior segment. Evaluation of initiation and maintenance then denotes the functional efficiency of the suspected area alone. Tests for maintenance of abduction give more definite reactions and are more reliable than those for initiation, which, as Inman, Saunders and Abbott have pointed out, is quite variable.

The reactions to all functional tests are brought into sharper focus when the examiner opposes the function with manual or other resistance.

The technic of functional evaluation is simple. In order to test initiation of abduction the flexed elbow is held against the side by the examiner and the patient is required to attempt abduction against this manual resistance in one plane of rotation after another until the complete range of rotation has been covered. Maintenance of abduction is tested by passively abducting the arm to 90 degrees, following which the patient, after first relaxing all muscles, is required to maintain the abducted position against both gravity and downward pressure by the examiner. All planes of rotation must be tested.

Confirmation and support for these functional tests may be obtained by having the patient attain full elevation in the position of quadruped extension, which is always possible. Then with a little help and by straightening up from the stooped position it will be found that maintenance of complete elevation in the erect position is also possible. But as the patient commences to lower the arm, thereby creating a functional demand for glenohumeral stabilization by the cuff, it will fall helplessly to the side if a gross tear is present, again provided the plane of humeral motion is such that the torn portion occupies the superior segment.

Interpretation of the reactions to such tests is not difficult when approached with a comprehension of several facts which commonly tend to confuse the picture:

1. No functional test is valid until the acutely painful phase subsides sufficiently so that pain does not interfere with muscle action (usually a matter of about two weeks).

2. All persons suffering from rupture quickly learn to initiate and maintain elevation by rotating the arm into a position such that the remaining intact cuff occupies the superior segment.

3. No rupture, with the exception of a complete avulsion, can be identified by demonstration of localized absence or derangement of function until the arm is rotated into a position creating functional demand on the ruptured portion.

4. Incomplete and small complete tears are characterized by pain limited to those rotational positions creating a functional demand on the injured portion. Localized weakness may be present but is seldom noticeable enough to be appreciable.

5. Ruptures up to 1 inch in length frequently are compensated for by the adjacent cuff attachments. The reaction to functional evaluation under such circumstances is weakness and pain localized to the appropriate segment of the rotation arc, producing a functional demand on the injured part.

6. Localized inability to maintain abduction against two finger resistance denotes loss of function in an appreciable portion of the cuff and usually a tear of at least 1 inch or more in length.

7. Localized inability to maintain abduction against gravity denotes a large tear usually involving the equivalent of two whole tendons.

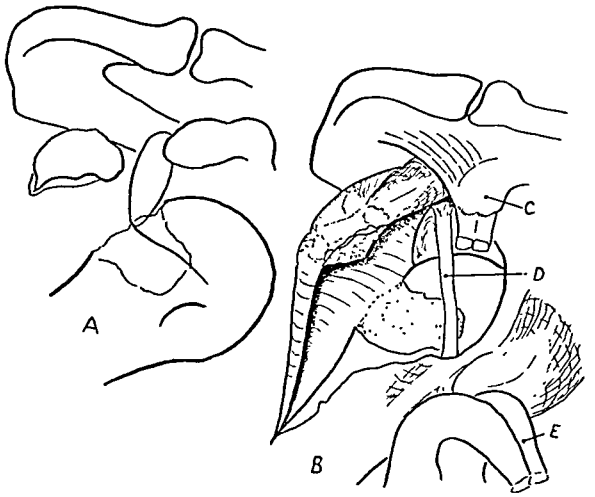

Fig. 2.—Dislocation with unretracted tuberosity fragment: *A*, x-ray; *B*, anatomic sketch; *C*, coracoid; *D*, biceps tendon; *E*, reflected coracobrachialis and short biceps head.

8. Complete inability to initiate or maintain abduction in any plane usually denotes a massive avulsion involving all or almost all of the cuff insertion.

SUPPORTIVE EVIDENCE

Most of Codman's hypothetical requirements fall into this category and are of great value, especially in equivocal cases. He has described them with such excellence that repetition would be superfluous. It has been found, however, that their evaluation is not without pitfalls for the inexperienced examiner. His "tender point" may be simulated by calcific deposit, local infection, minute fracture not apparent by x-ray, bone tumor, bursitis or minor muscle tear. The "sulcus" may be simulated by bundles of deltoid fibers, the long head of the biceps or a thickened redundant bursal roof. Palpation of the greater tuberosity through an atrophic deltoid demonstrates an excellent "eminence" even with an intact cuff. The "jog and wince on motion" are encountered frequently with subacute or chronic calcific deposits. "Palpable crepitus on motion" is an excellent and important sign but not until one learns to appreciate the difference between the crepitus produced by chronic inflammatory thickening in the bursal wall and that produced by palpation of a mobile tab of torn tendon. "Faulty scapulohumeral rhythm" is present in all painful shoulders regardless of cause. "Little if any restriction when stooping" is constantly true of ruptures but is also true of certain other minor traumas simulating the clinical picture of a tear. "No painful symptoms prior to the accident" was a constant history in Codman's cases. In about 50 per cent of the proved ruptures in the present series symptoms were complained of prior to their accident, and this was understandable in that many of them were found to have a recent extension superimposed on an old tear.

Muscle atrophy and atony constitute an important differential sign, as Codman also pointed out. General disorders of the shoulder usually result in atrophy of the deltoid. Disuse results in diffuse atrophy, most apparent in the deltoid. Rupture of the cuff results in selective atrophy of the involved intrinsic muscle or muscles unaccompanied by a corresponding deltoid myopathy. This phenomenon becomes appreciable to both inspection and palpation between the ends of the second and third weeks and contributes important evidence in support of the diagnosis. Bursal disorders produce deltoid atrophy without a corresponding change in the bellies of the intrinsic rotators.

Codman required a negative x-ray as one of the conditions to be fulfilled. Exception must be taken to the literal implications of such a flat statement. Ruptures not uncommonly occur in conjunction with other bone and joint lesions and, although they may be the most disabling lesion present, are prone to be missed when attention is distracted by the obvious bony pathologic change evidenced by the x-ray film. Roentgen examination not only is of great value in ruling out other simulating conditions but often supplies supportive and, at times, pathognomonic evidence of a torn cuff. Early ruptures, especially in younger persons, are apt to be characterized by a completely negative x-ray. Ruptures of long duration or those resulting from minor trauma in the older age group almost always are characterized by degenerative bone changes in the tuberosity at the point of tendon avulsion. Such a finding in itself means little but, when accompanied by compatible clinical signs, constitutes real evidence in support of the diagnosis.

It has been demonstrated that a positive clinical diagnosis of tear can be confirmed by roentgenography. A series of suspected cases was examined by fluoroscope immediately after injection of 50 cc. of filtered oxygen under sterile auspices into the cavity of the shoulder joint. When the arm was manipulated into the appropriate position it was possible to visualize the escape of gas from the joint cavity through the rupture into the bursal cavity. No such phenomenon was observed in the small number of controls used for comparison. All positive and some negative results were confirmed by operation, and although the number of cases in which the experiment was done was small its efficiency as a diagnostic procedure seemed reasonably certain.

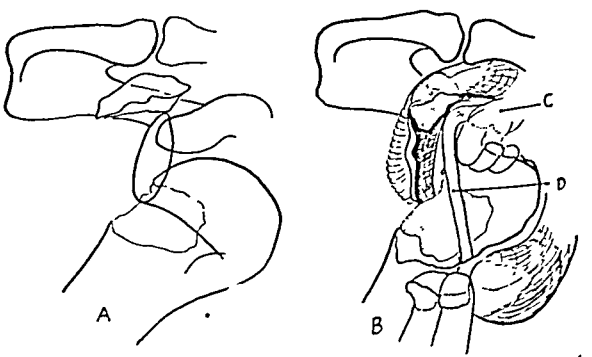

Fig. 3.—Dislocation accompanied by retracted tuberosity fragment: *A*, x-ray; *B*, anatomic sketch; *C*, coracoid; *D*, long head of biceps.

Subsequent improvement in the methods of functional evaluation have made any such test, accompanied as it is by a potential risk of infection, unnecessary.

Roentgen examination is most important in the diagnosis of ruptures associated with fracture or dislocation. Not uncommonly a torn cuff is the most disabling factor in a complex shoulder injury. Usually clinical identification of the rupture is impossible until long after

the bony lesion has healed. Frequently a positive roentgen diagnosis is possible at the first examination.

Dislocation at the shoulder accompanied by a fracture of the greater tuberosity (69 times in 439 dislocations in the records of the Presbyterian Fracture Clinic) almost always is accompanied by a torn cuff. Most such tears do not require operative repair, but others result in serious disability unless attended to.

They may be divided into three main groups, each of which can be identified by x-rays taken prior to reduction of the dislocation.

The largest group requires no operative intervention. It includes all those cases in which the tuberosity fragment conforms to the position indicated in figure 2, neither retracted up under the acromion nor pulled downward as far as the dislocated humeral head. The anterior joint capsule usually has been found to be intact and the dislocation to be essentially intra-articular. The abnormal position of the humeral head results from an avulsion of all its superior and posterior attachments as indicated in the anatomic sketch. Reduction of the dislocation results in anatomic reposition of the tuberosity fragment and also of the edges of the longitudinal cuff rent so that no repair is necessary.

The second group includes those cases with the tuberosity fragment retracted up under the acromion as depicted in figure 3. Such a film constitutes definite evidence of a large tear across the cuff (without which no such retraction is possible) and usually a massive avulsion of the cuff from the humeral head as indicated in the anatomic sketch. Early repair is essential to a good result.

The third group includes the cases wherein the tuberosity fragment is pulled downward and remains relatively unseparated from the humeral head (fig. 4). Such a lesion may correspond to the "false dislocation" described by Codman, and when this is the case a lengthy rim rent or deep surface tear commonly accompanies the dislocation and may result in delayed or incomplete recovery. At times the pathologic change of the soft parts consists of a small longitudinal rent and an avulsion of the posterior capsule or glenoid labrum as indicated in sketch 2 in addition to an anteroinferior capsular tear. Occasionally there is an avulsion of the cuff attachments from the tuberosity as in sketch 3. The latter condition may be suspected when reduction of the dislocation is accompanied by a failure of the tuberosity to resume its normal anatomic position.

Certain dislocations are reduced when first seen. Incomplete reduction or persistent subluxation of the humeral head, even if only slight in amount, usually is indicative of a large tear and in an elderly person, especially if degenerative changes are apparent in the humeral head, is almost pathognomonic of a complete cuff avulsion.

OTHER CONDITIONS REQUIRING DIFFERENTIATION

A rupture of significant size resulting in demonstrable functional derangement produces a clinical picture not closely simulated by any other condition. Small complete or incomplete tears resulting in equivocal functional defects often require differentiation from the following conditions:

1. Painful calcific deposits. These may be identified by adequate x-ray films. More than a hundred deposits have been explored. Only one was accompanied by a torn tendon. Therefore it seems reasonable to assume that the presence of a calcific deposit makes a rupture in the same shoulder highly improbable.

2. Minor fractures, especially undisplaced fissures in the greater tuberosity, which usually may be identified by x-ray.

3. Rupture of deltoid or intrinsic muscle fibers. Either may produce signs and symptoms suggestive of a small rupture in the cuff, and this seems especially true in younger persons. Four patients under the age of 30 have been subjected to exploration for the purpose of doing an early repair of a torn cuff in whom the pathologic change consisted of a hematoma in the under surface of the deltoid and in 1 case of the belly of the supraspinatus. A minimum of two weeks' delay before deciding on operative intervention greatly minimizes the risk of this mistake.

4. The so-called "frozen shoulder." No tear has been encountered in exploration of a stiffened shoulder, and none of the 60 proved ruptures presented had any significant limitation of passive motion.

5. Certain forms of chronic bursitis characterized by inflammatory thickening of the bursal roof, which is thrown into folds on motion of the arm. The result is an internal derangement of the articulation between cuff and acromion or acromial ligament, and the clinical picture produced is difficult to differentiate from that of a small tear. Exploration and excision of the bursa constitute not only the final differentiation but also the most efficient therapy for the condition.

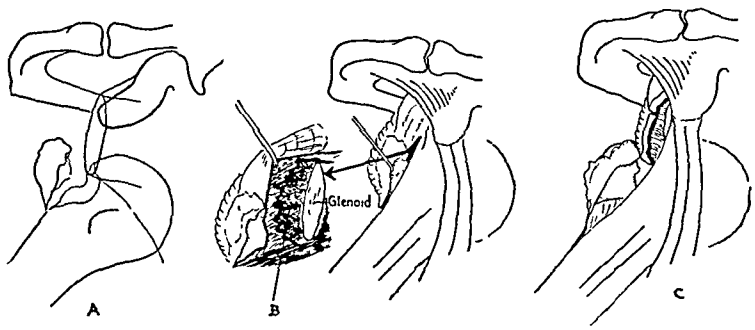

FIG. 4.—Tuberosity fragment pulled downward and remaining relatively unseparated from the humeral head. *A*, x ray; *B*, interior of joint cavity, posterior capsule avulsed from glenoid labrum allowing tuberosity to follow humeral head; *C*, avulsion of cuff tendons allowing tuberosity to follow humeral head.

INDICATIONS FOR OPERATIVE THERAPY

Establishment of a positive diagnosis does not afford adequate indication for operation. The symptoms and disability resulting from many ruptures subside spontaneously. At least half the patients in whom an early diagnosis of rupture has been made in our clinic have maintained the signs but eventually lost most of the symptoms of the lesion. Almost all have been adequately followed, and it has been apparent that, while such subsided lesions may produce occasional mild symptoms related to weather or overuse, no disabling exacerbations of pain are liable to occur unless the shoulder is subjected to another injury.

The only definite indication for operation consists of pain or disability sufficient in duration or severity to make the procedure worth while from the patient's point of view. This indication may exist in the presence or absence of a clearcut diagnostic picture. Even in the absence of definitive signs the diagnosis of internal derangement of the shoulder joint may be made and, as in the case of the knee joint, warrants exploration and eradication of existing pathologic conditions.

SUMMARY

Under the auspices of a plan for diagnosis and evaluation of the torn shoulder cuff, 64 shoulders were explored with a preoperative diagnosis of rupture. The diagnosis was incorrect in 4 cases.

180 Fort Washington Avenue.

ABSTRACT OF DISCUSSION

DR. JAMES E. M. THOMSON, Lincoln, Neb.: It is rather interesting that within the course of a single year there should have been brought into the literature and to you today such epochal discussions involving a new and revolutionary understanding of these shoulder cuff lesions. I refer to the recently published work of Inman, Saunders and Abbott and also to that of Dr. David Bosworth and now to the author of this paper: in particular, to their anatomic understanding of the function of the shoulder, in the first instance, and secondly the surgical approach and the possibilities of operative repair. Lastly this paper by Dr. McLaughlin contributes significantly to the diagnosis and indications for operation. This is one condition in which there is no hurry about operation. Usually a pathologic condition has existed for a long time prior to the injury, and we can take time to study the possibilities of its future and its repair. Dr. McLaughlin has brought out some very pointed observations with regard to the indications for operation and particularly to the fact that an early diagnosis cannot be made, that evaluation of the tear can be made by a functional rotary examination of the various movements of the shoulder. Since hearing the author's paper last year I have had the pleasure of following his procedure and approach. Those to whom it is new will find that they are viewing the shoulder from a totally different view; that is, from above and into the shoulder. The exposure is so broad that one sees much that may be confusing. In the series in which I have operated tremendous tears were found that I never would have thought possible in a shoulder. From this observation one cannot but wonder whether perhaps many of the smaller tears do not heal spontaneously and whether that is not the reason one feels that it is appropriate to wait until one makes a positive diagnosis before operating. I am still confused in trying to make an accurate diagnosis because I have not been able to demonstrate the small tears, but I have had great satisfaction in using this exposure and repairing satisfactorily massive tears of the shoulder cuff. This paper is epochal in its subject matter and the understanding of this very complex problem of internal derangement of the shoulder.

DR. EDWIN W. RYERSON, Chicago: The first thing that struck me in reading the paper was the probability that the women of Boston are a little bit tougher than the women of New York, because Codman never reported this injury in any women. Also that probably the New York women belong in the class of laborers more than the ones in Boston do. I have not seen this happen in any women except one whom I saw two weeks ago who fell from a horse and had ruptured part of her musculotendinous cuff. The other important point was the careful consideration given by Dr. McLaughlin to the nonoperability of so many of these cases, and it is true that many of them, especially in older people, are the result of a degeneration of the musculotendinous cuff due to age, occupation and arduous work. If one trie to repair these tears one does not, as a rule, get a very good result. I am less and less in favor of operating on the older people with the degenerative tendency.

DR. HARRISON L. MCLAUGHLIN, New York: Dr. Thomson has brought up the question of the diagnosis of small and incomplete ruptures. I know of no method for their certain diagnosis. This paper was based on a series of cases preoperatively diagnosed as rupture and in most of them there were fairly extensive lesions. In many other cases exploration has been done in our clinic with a preoperative diagnosis of internal derangement of the shoulder, and it has been in this group of cases that most of the small and incomplete ruptures have been encountered.

THE TREATMENT OF EMPYEMA THORACIS WITH PENICILLIN

CAPTAIN MARTIN J. HEALY JR.
AND
CAPTAIN HARRY L. KATZ
MEDICAL CORPS, ARMY OF THE UNITED STATES

The recent advances in the therapy of pneumonia with the sulfonamide compounds have reduced the frequency of the dreaded complication empyema thoracis. However, the management of this complication still remains a taxing problem to the surgeon and internist. The treatments advocated vary from the extremes of aspiration alone to the use of wide thoracotomy. Regardless of the procedure used, the aim in the management of acute empyema is essentially the same; that is, to institute efficient drainage of the pleural cavity, to permit the lung to reexpand and to obliterate the free pleural space in order to prevent the development of chronic empyema.

The therapeutic value of penicillin in the treatment of cases of pneumococcic, streptococcic and staphylococcic infections has been well established. The most recent results obtained from its use have been summarized in the detailed report by Keefer and his associates.[1] The efficacy of penicillin in the management of empyema thoracis was mentioned in the work of Lyons,[2] who reported its use in 2 cases of nonbacteremic staphylococcic empyema with improvement. Dawson and Hobby [3] report the use of penicillin intrapleurally in 2 cases of pneumococcic empyema and in 1 case of staphylococcic empyema, with gratifying results. Tillett, Cambier and McCormack [4] reported the use of penicillin intrapleurally in 8 cases of pneumococcic empyema, in 7 of which the infection was controlled by local therapy without surgical drainage. Six of the patients recovered completely, while 1 patient insufficiently treated with penicillin had a recurrence of infection necessitating surgical drainage.

3. Dawson, M. H., and Hobby, G. L.: The Clinical Use of Penicillin, J. A. M. A. **124**: 611 (March 4) 1944.
4. Tillett, W. S.; Cambier, M. J., and McCormack, J. E.: The Treatment of Lobar Pneumonia and Pneumococcal Empyema with Penicillin, Bull. New York Acad. Med. **20**: 142 (March) 1944.

This study comprises observations on 5 consecutive cases of empyema thoracis treated with intrapleural instillations of penicillin without surgical drainage. The etiologic agents varied considerably; in 2 cases the empyema was caused by nonhemolytic Staphylococcus aureus, 1 case by pneumococcus type III, 1 by a nonhemolytic streptococcus and 1 by a mixed infection containing a nonhemolytic streptococcus and hemolytic Staphylococcus aureus. In addition to the intrapleural instillation of the drug, parenteral penicillin was administered to patients who were felt to have underlying unresolved pneumonia, bacteremia or other complicating infections accessible to the blood stream.

Penicillin was supplied in the form of an amorphous powder in sealed ampules containing 100,000 units each. Solutions for parenteral or intrapleural use were prepared on the day of administration and kept constantly in the refrigerator at 5 C. For parenteral use the dry powder was dissolved in sterile saline solution so that 1 cc. contained 5,000 units. The individual dosage varied from 20,000 to 25,000 units administered every three hours by the intramuscular route. Solutions for intrapleural use contained 500 units per cubic centimeter and the usual intrapleural instillation contained 50,000 units dissolved in 100 cc. of sterile saline solution. Thoracentesis was accomplished under sterile precautions by entering the empyema cavity at the lowest possible level with a 15 or 17 gage needle. The pleural exudate was aspirated as completely as possible, sterile saline irrigations being used when necessary to thin out thick pus, which frequently obstructed the bore of the needle with fibrin plugs. Following aspiration, the penicillin solution was instilled into the pleural cavity. This procedure was repeated, usually on alternate days, and the frequency and duration of treatment depended on the response of the patient as manifested by fall of temperature, clinical appearance, bacteriology of the pleural exudate and the amount and rapidity of fluid reaccumulation.

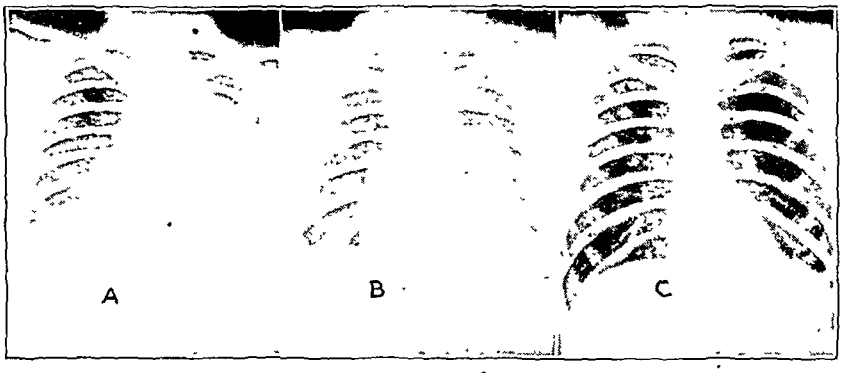

Fig. 2 (case 1).—*A*, 13th day of illness: a massive empyema on the left side with complete absence of aeration up to the second rib anteriorly. *B*, 18th day of illness: a large portion of the fluid has been aspirated; the remainder is loculated posteriorly. *C*, 92d day of illness: end result, normal chest.

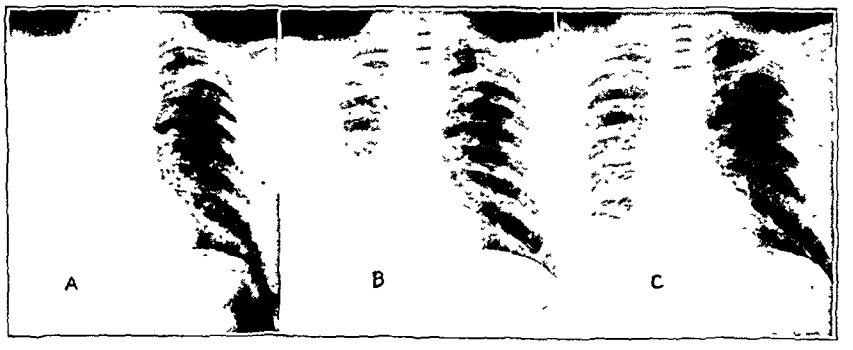

Fig. 3 (case 2).—*A*, 36th day of illness: a massive empyema on the right side, with total obliteration of pulmonary detail. *B*, 49th day: progress during therapy; much of the exudate has been aspirated; the fluid level is now at the 4th rib anteriorly. *C*, 59th day: the right diaphragmatic leaf is smooth in contour; minimal pleural thickening is noted in the region of the costophrenic sinus.

REPORT OF CASES

CASE 1.—A white man aged 23, diagnosed as having empyema secondary to bronchopneumonia, left lower lobe, nonhemolytic Staphylococcus aureus, was hospitalized on Dec. 4, 1943 because of pain in the left chest, fever, malaise, chills and cough productive of blood tinged sputum of one day's duration. Physical examination revealed signs of left lower lobe consolidation, which was confirmed by chest x-ray examination. Sulfadiazine therapy was instituted without therapeutic effect on the clinical course. The patient progressively developed dyspnea, orthopnea and cyanosis, and the temperature varied between 100 and 104.5 F., the pulse rate from 120 to 140 per minute and the respiratory rate from 30 to 40 per minute. Pneumococci could not be typed from the sputum, but many colonies of Staphylococcus aureus were present on culture. Sulfadiazine was discontinued on the ninth day of illness after a total dosage of 56 Gm. and penicillin therapy was started (fig. 1). On the ninth day of his illness he received 200,000 units of penicillin: 160,000 units intramuscularly (20,000 every three hours) and 40,000 units intravenously. The same dosage was repeated three days later, but the temperature continued to be septic and the patient appeared toxic and acutely ill. At this time a massive left pleural effusion was noted on x-ray examination (fig. 2*A*).

The patient was transferred to the hospital for surgical drainage and came under our observation on the 17th day of his illness. At that time he was acutely ill, dyspneic, orthopneic and cyanotic, and clubbing of the fingers was demonstrable. His temperature was 101 F., and the white blood cell count was 12,300 with 76 per cent polymorphonuclear leukocytes. Examination revealed the presence of fluid throughout the entire left chest. Thoracentesis was performed and 175 cc. of thick, yellow, purulent exudate was aspirated and 45,000 units of penicillin dissolved in 90 cc. of sterile saline solution was instilled into the pleural space. Aspiration and instillations were repeated on the 20th, 25th, 29th and 31st days of illness, the amount of fluid removed varying from 70 to 180 cc. and the dosage of penicillin from 15,000 to 50,000 units. The pleural exudate revealed numerous colonies of nonhemolytic Staphylococcus aureus on culture. On subsequent aspiration the fluid became progressively thinner and cultures revealed diminishing numbers of bacterial colonies. Fluid aspirated on the 29th and 31st days of illness was thin, serous and sterile on culture.

The temperature declined by lysis and the patient's general condition progressively improved. He gained 35 pounds (16 Kg.) in weight and was discharged to duty three months after the completion of treatment. X-ray studies revealed progressive diminution in the size of the empyema cavity (fig. 2*B*) and a chest plate taken three months after treatment revealed essentially normal lung fields (fig. 2*C*). Diaphragmatic excursions were normal and there was no diminution of vital capacity.

At the onset the patient apparently developed a primary atypical pneumonia, which was complicated on or about the 13th day of illness by a Staphylococcus aureus empyema. This complication was not prevented by parenteral penicillin in the dosage given. Aspiration

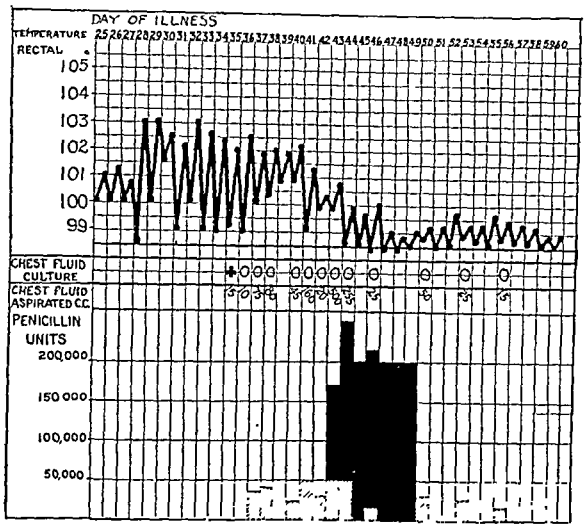

Fig. 4 (case 2).—Course in case of lobar pneumonia, empyema, pneumococcus type III. Penicillin: solid blocks, parenteral; shaded, intrapleural.

of the exudate and intrapleural instillation of penicillin resulted in an apparently complete recovery without surgical intervention.

CASE 2.—A white man aged 32, diagnosed as having lobar pneumonia, empyema, pneumococcus type III, was hospitalized on Oct. 20, 1943 because of chills, fever, malaise and cough productive of sputum of one day's duration. Examination and a chest x-ray film showed consolidation of the right lower lobe. The temperature was 104 F. and the white blood cell count was 18,000 per cubic millimeter with 80 per cent polymorphonuclear leukocytes. Sputum typing revealed type III pneumococci. He was treated with a total dose of 60 Gm.

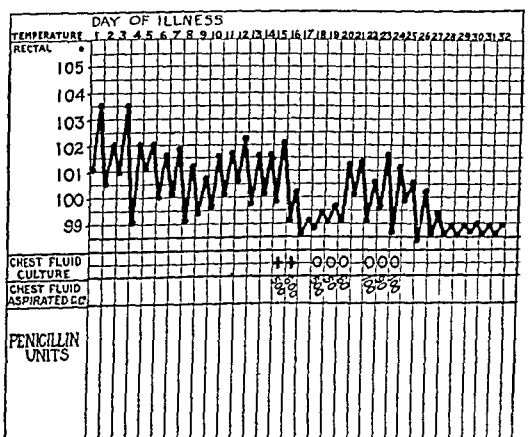

Fig. 5 (case 3).—Course in case of lobar pneumonia, empyema, mixed infection, pneumococcus type I, Staphylococcus aureus. Penicillin intrapleural.

of sulfadiazine over a period of twelve days. The temperature subsided by lysis and returned to normal after nineteen days. However, on the 22d day of illness the temperature began a gradual staircase rise and further examination revealed signs of fluid in the right chest. Thoracentesis on the 26th day yielded 500 cc. of thick, greenish exudate from which was cultured pneumococcus type III.

The patient came under our observation on the 34th day of his illness, at which time he was critically ill, cyanotic, dyspneic and orthopneic. There was clubbing of the fingers. The temperature was elevated to 103 F. and there were signs of a massive empyema of the right chest (fig. 3 *A*). Aspiration of the exudate and intrapleural penicillin instillations were instituted. Figure 4 indicates the plan of therapy and the clinical course of the patient. Thoracentesis was performed every one to two days for a period of two weeks, the amount of exudate varying from 15 to 500 cc. and the quantity of penicillin instilled from 15,000 to 50,000 units. The pleural fluid, which was at first thick, creamy and greenish, gradually became thin, clear and serous in consistency, and serial cultures were repeatedly sterile after the first instillation of 45,000 units of penicillin. Six days after the inception of local therapy the patient suddenly developed increased coughing and expectoration of mucopurulent sputum. As the temperature was still elevated, the patient was begun on parenteral penicillin

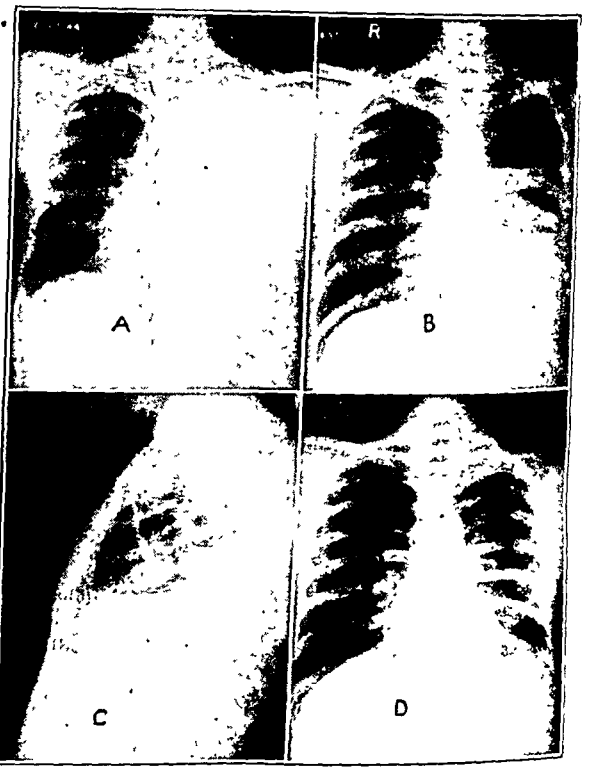

Fig. 6 (case 3).—*A*, 6th day of illness: a massive left empyema with displacement of the mediastinum to the right. *B* and *C*, 13th day: following aspiration of pleural exudate, two distinct fluid levels are present revealing anterior and posterior loculations; it was necessary to instil penicillin into each pocket. *D*, fifteen weeks after treatment: normal chest except for minimal pleural thickening.

25,000 units intramuscularly every three hours. The following day the patient coughed up 500 cc. of the same thick exudate; gas was aspirated from his chest cavity (fig. 3 *B*). Despite the development of the bronchopleural fistula, serial cultures of the pleural fluid remained sterile. Within two days the fistula closed spontaneously, as evidenced by cessation of the cough and expectoration. Penicillin was continued parenterally for three more days, but repeated aspiration and instillations of the drug were continued several days apart on four occasions to insure against reinfection. The patient made a rapid recovery, maintained a normal temperature and gained 45 pounds (20 Kg.) in weight. X-ray examination four months after the onset of illness showed the chest to be normal with the exception of slight pleural thickening in the region of the costophrenic sinus (fig. 3 *C*). Five months after illness the patient was on full active duty with no complaints.

A pneumococcus type III empyema complicated by a widely patent bronchopleural fistula recovered under parenteral and intrapleural penicillin therapy. The

pleural fluid remained sterile after the first instillation of 45,000 units of penicillin despite the presence of the fistula. Complete symptomatic recovery occurred within four weeks after the institution of penicillin therapy.

CASE 3.—A white man aged 37, diagnosed as having lobar pneumonia, empyema, mixed infection, pneumococcus type I, Staphylococcus aureus, was hospitalized on Feb. 18, 1944 with complaints of malaise, chills, fever and pain in the left chest. On admission he was acutely ill and the temperature was elevated to 102 F. Examination of the chest revealed the characteristic signs of a left lower lobar pneumonia. Chest x-ray films confirmed this diagnosis, and type I pneumococci were found in the sputum. The white blood cell count was 20,500 per cubic millimeter with 78 per cent polymorphonuclear leukocytes. He was treated with 74 Gm. of sulfadiazine over a period of twelve days without therapeutic response. He remained decidedly toxic and dyspneic and the temperature was septic, with intermittent elevations to 103 F. On the 6th day of illness he developed characteristic signs of a massive empyema of the left chest (fig. 6 *A*). Thoracenteses were done on the tenth and fifteenth days of illness, yielding on each occasion 500 cc. of thick, tenacious, creamy, greenish exudate, cultures of which revealed pneumococcus type I.

The patient came under our observation on the 16th day of his illness and was started immediately on aspiration and intrapleural penicillin therapy. At the time of the first treatment 660 cc. of thick, greenish fluid was aspirated and 50,000 units of penicillin instilled into the pleural cavity. Culture of the aspirated material revealed both type I pneumococcus and nonhemolytic Staphylococcus aureus. This and subsequent aspirations were difficult, owing to the thickness of the exudate, and irrigation with isotonic solution of sodium chloride was utilized to facilitate its evacuation. Figure 5 indicates the scheme of therapy followed and the clinical response of the patient. Ten aspirations in all were performed, yielding variously from 50 to 650 cc. of exudate. Instillations of penicillin were carried out on seven occasions, a total of 350,000 units.

Although the chest fluid was sterilized after the first instillation the patient remained acutely ill, toxic and febrile. The reason for the failure to respond promptly became apparent when subsequent chest films revealed two definite fluid levels, indicative of large fluid loculations anteriorly and posteriorly (fig. 6 *B* and *C*). Thoracenteses were now accomplished from each pleural pocket and penicillin instilled into each loculation on alternate days.

From this point on the temperature gradually subsided, the patient's general condition progressively improved and he remained afebrile. Fifteen weeks after therapy a chest x-ray taken prior to return to active duty showed a normal chest except for minimal pleural thickening (fig. 6 *D*). Fluoroscopy revealed normal diaphragmatic excursions.

A mixed type I pneumococcus and nonhemolytic Staphylococcus aureus empyema with loculations was treated with intermittent aspiration and instillation of a total of 350,000 units of penicillin intrapleurally without surgical intervention. The pleural fluid was sterilized after the first treatment with 50,000 units of the drug, but the temperature remained elevated until adequate evacuation of the exudate from both pleural loculations was accomplished.

CASE 4.—A white man aged 29, diagnosed as having empyema, nonhemolytic streptococcus, was hospitalized on Jan. 7, 1944 because of symptoms of cough, headache, malaise and sore throat of seven days' duration. On the day of admission he noted a chill and a stabbing pain in the left chest, which was aggravated on deep inspiration and coughing. The temperature was elevated to 105 F., respirations were labored and the mucous membranes were cyanotic. Physical examination and a chest x-ray film revealed evidence of consolidation of the left lower lobe. Cultures of the sputum revealed nonhemolytic streptococci. In addition to general supportive measures, which included parenteral fluid and oxygen, the patient was given 31 Gm. of sulfadiazine over a period of four days without beneficial response. It was now clinically apparent that the patient was suffering from a very virulent infection, and he continued critically ill, toxic, dyspneic and cyanotic. On the 10th day of illness he developed signs of a massive pleural effusion on the left side and a spread of the pneumonic process to the right, middle and lower lobes (fig. 7 *A*). Thoracentesis on the same day yielded 1,275 cc. of thin, blood tinged fluid which contained numerous nonhemolytic streptococci on smear and culture.

In view of the moribund condition of the patient and because of evidence of an underlying fulminating pneumonic process, sulfadiazine was discontinued and penicillin therapy was instituted both parenterally and intrapleurally. Figure 8 demonstrates the scheme of penicillin therapy and the clinical response of the patient. Eight thoracenteses were performed every one to three days during the ensuing thirteen days, the amounts removed varying from 60 to 550 cc. On each occasion 50,000 units of penicillin was instilled except on the second day of treatment, when 100,000 units was given. Over a period of fourteen days he received a total of 2,500,000 units of penicillin parenterally and 450,000 units intrapleurally. The pleural fluid, which had thickened during the first four days of the empyema, rapidly became thin and serous in consistency and remained sterile on culture following the first intrapleural instillation of penicillin. The temperature gradually subsided by lysis and his general condition progressively improved.

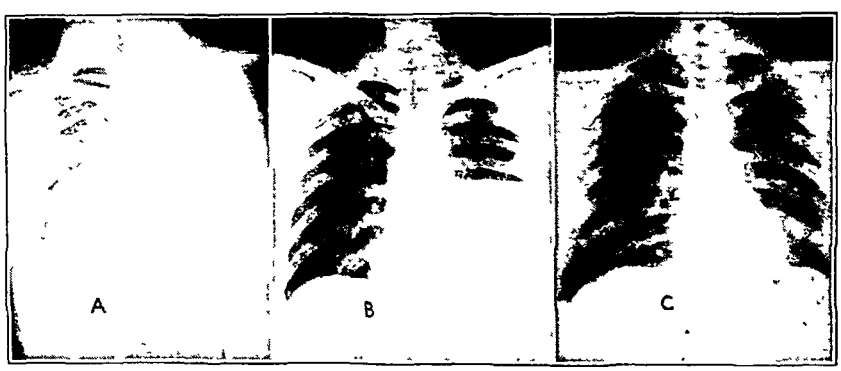

Fig. 7 (case 4).—*A*, 10th day of illness: a massive empyema on the left, with displacement of the heart and mediastinum to the right; a patchy type of consolidation involves almost the entire right lung. *B*, 34th day of illness: appearance of chest at the time of first relapse; there is a pyopneumothorax on the left with a fluid level at the 7th rib posteriorly; the heart and mediastinum are now in the midline and the right lung is clear. *C*, appearance of chest four months after onset of illness, showing a normal chest with the exception of slight pleural thickening in the left cardiophrenic angle.

On the 33d and 47th days of illness the patient had recrudescences of temperature elevation associated with reaccumulation of pleural fluid which remained sterile on culture (fig. 7 *B*). Three instillations of 50,000 units of penicillin were administered on alternate days during each of these relapses. On both occasions this treatment resulted in prompt subsidence of temperature and in clinical improvement of the patient.

Subsequently his temperature remained normal, he gained 29 pounds (13 Kg.) and he manifested no signs of decreased pulmonary function. The vital capacity was normal, there was no evidence of exertional dyspnea and the patient was returned to active duty five months after the onset of his illness. He was still on active duty and free of symptoms ten months after his illness. The final chest x-ray (fig. 7 *C*) revealed total reexpansion of the left lung and complete clearing of the

empyema with minimal residual thickening of the pleura in the cardiophrenic angle. Fluoroscopy revealed a normal range of diaphragmatic motion.

This critically ill patient with a nonhemolytic streptococcus pneumonia and empyema was treated with 2,500,000 units of penicillin parenterally and 750,000 units intrapleurally over a period of forty-one days.

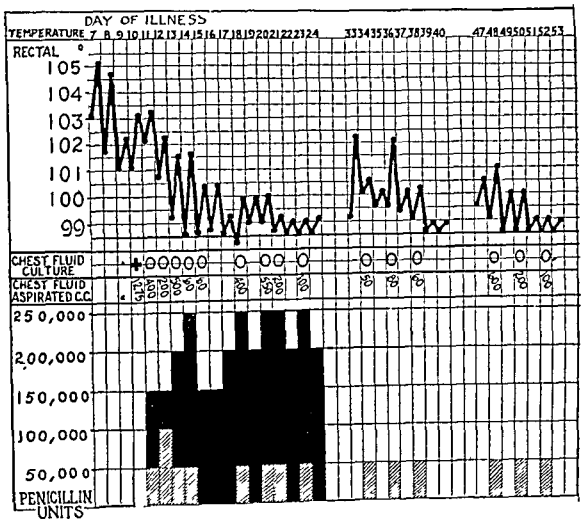

Fig. 8 (case 4).—Course in case of empyema, nonhemolytic streptococcus Penicillin: solid blocks, parenteral; shaded, intrapleural.

He recovered completely, showing a substantially normal chest, functionally and anatomically. The use of such massive doses of penicillin was considered necessary in view of the critical status of the patient. Following the first instillation of penicillin, the pleural exudate remained sterile even at the time of two subsequent relapses with reaccumulation of fluid.

Case 5.—A white man aged 20, diagnosed as having empyema, mixed infection, left chest, nonhemolytic streptococcus, hemolytic Staphylococcus aureus, was first hospitalized on April 27, 1943 with a diagnosis of bronchopneumonia of the left lower lobe. The course was febrile, the white blood cell count varied from 18,000 to 30,000 per cubic millimeter and repeated sputum cultures revealed colonies of nonhemolytic streptococci. He was treated with a total of 52 Gm. of sulfadiazine over a period of seven days without therapeutic effect. Three weeks later he developed a massive pleural effusion (fig. 9 *A*). Thoracotomy was performed with the institution of closed intercostal drainage, which was unsuccessful in controlling the infection. Three weeks later resection of the eighth rib was performed and open tube drainage established. Temporary improvement followed, but despite persistent local treatment the pleural cavity could not be obliterated and the patient went on to develop an extensive chronic empyema. Drainage was profuse, cultures of the pus showing hemolytic Staphylococcus aureus and nonhemolytic streptococci.

The patient came under our observation six months after the onset of his illness. He was considerably underweight and showed intermittent temperature elevations to 101 F. A draining sinus tract was noted at the site of the previous thoracotomy. Instillation of iodized oil revealed a well demarcated, irregular, tubular empyema cavity 2.5 cm. in diameter (fig. 9 *B*). Culture of the purulent drainage from this tract revealed many colonies of hemolytic Staphylococcus aureus.

Local therapy was instituted, consisting of daily thorough aspiration of retained exudate by means of a small catheter and instillation of penicillin solution 250 units per cubic centimeter to the capacity of the pleural pocket. The total volume varied from 25 to 70 cc. over a period of eleven days, and the total amount of penicillin instilled was 104,600 units. Serial cultures of the aspirated exudate showed a progressive diminution in the total number of bacterial colonies until, near the completion of therapy, only an occasional colony was noted. In order to facilitate reexpansion of the lung and obliteration of the pleural space an occlusive dressing was applied to the sinus opening and an oxygen lavage of the pleural pocket was performed. The sinus tract gradually healed, and the patient became afebrile and symptomatically improved. Serial chest x-rays showed progressive, complete obliteration of the empyema cavity but a zone of thickened pleura remained (fig. 9 *C*).

Except for persistent anorexia and failure to gain weight adequately, the patient remained clinically improved, afebrile and ambulatory for four months following treatment. After that time he suddenly developed pronounced malaise, pain in the left chest and a sudden rise in temperature to 103 F. Examination and a chest x-ray film (fig. 9 *D*) revealed a large reaccumulation of fluid in the left pleural space. Aspiration yielded over 100 cc. of thick, greenish exudate, which showed hemolytic Staphylococcus aureus on culture. Fifty thousand units of penicillin was instilled on three occasions two days apart for a total of 150,000 units. The temperature subsided promptly after the second treatment and clinically the patient was much improved. The pleural exudate remained sterile on culture after the second instillation of penicillin.

Although control of the acute recurrence was obtained by the use of intrapleural penicillin, it was deemed advisable that open thoracoplasty be performed in view of the protracted clinical course and the presence of advanced structural changes within the chest. Accordingly he was transferred to a thoracic surgical center for consideration of such therapy.

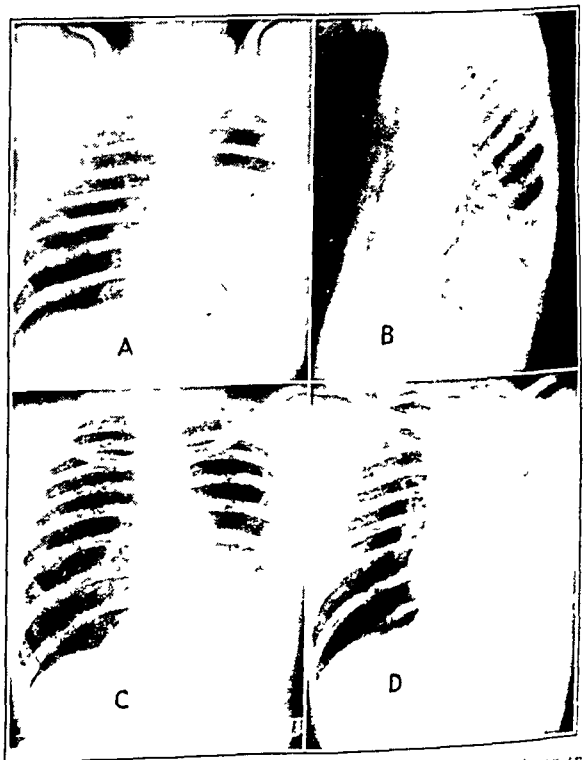

Fig. 9 (case 5).—*A*, 4th week of illness, showing pyopneumothorax on the left. *B*, end result five months after surgical drainage; iodized oil reveals a long tubular, pleural pocket extending from 3d rib posteriorly to the sinus opening in the 8th interspace. *C*, following penicillin therapy; chronic empyema cavity obliterated; a wide lateral zone of thickened pleura remains. *D*, four months after penicillin therapy: there is an extensive recurrence of fluid in the left lung.

This patient, with a mixed infection empyema containing a nonhemolytic streptococcus and a hemolytic Staphylococcus aureus, received apparently adequate surgical drainage but went on to develop an extensive chronic empyema. Intrapleural penicillin instillations resulted in closure of the pleural cavity and control of

the disease for a period of four months. At the end of this time there was an acute flare-up of the empyema, which again was controlled by intrapleural penicillin. The clinical course in this case would seem to indicate that, although a chronic empyema cavity may be sterilized and obliterated by local penicillin therapy, still recurrences of bacteriologically active infection may take place.

COMMENT

In observing the progress of these 5 cases, several points of importance in therapy became evident. It was considered important that treatment should be instituted at the earliest possible moment after the diagnosis of empyema had been established clinically and exudate obtained by aspiration. The organisms commonly causing empyema are susceptible to penicillin, and therapy need not await the bacteriologic identification of the etiologic agent.

Aspiration should be repeated at daily or two day intervals, depending on the amount and consistency of the exudate, the rate of reaccumulation of fluid and the clinical response of the patient. Thoracenteses should be performed at the lowest possible point in the empyema pocket, preferably under fluoroscopic control, using a large gage needle to facilitate aspiration. Irrigation with isotonic solution of sodium chloride was found to dilute thick, tenacious exudate and thus facilitate its aspiration. As much fluid as possible should be removed at each tapping, with the precaution that, in early cases with massive empyema, rapid removal of excessive amounts of fluid may result in mediastinal embarrassment. If a multilocular empyema exists, efforts must be made to aspirate each pocket thoroughly. Aspirations should continue until fluid does not reform. It has been observed, however, that small amounts of thin, sterile, serous fluid will be spontaneously absorbed by the patient within a short time.

Penicillin should be instilled after each aspiration at least until subsequent cultures of the fluid are proved to be sterile and the patient is clinically improved. The amount of the drug and the number of instillations necessary will vary with the clinical severity of the case and the type of organism involved. From 35,000 to 50,000 units was the dosage most frequently used and in our cases was found sufficient to effect sterilization of the exudate, even in the presence of a massive empyema.

With the therapy used the acute episode of empyema was controlled promptly in all 5 cases, as evidenced by fall in temperature, white blood cell count and sedimentation rate to normal levels, clinical improvement of the patient, rapid loss of exudate and reexpansion of the collapsed lung. In case 5 local treatment of an extensive chronic empyema resulted in arrest of the disease for four months, after which time an acute flare-up occurred. It is of interest that this secondary episode was also promptly controlled by intrapleural penicillin. However, because of the extensive underlying pleural thickening already present further radical surgery was deemed advisable to obtain obliteration of the chronic empyema cavity.

Following treatment, cases 2, 3 and 4 showed minimal pleural thickening, while the chest x-ray in case 1 was normal. In these 4 cases there was no deformity of the chest nor any diminution of the vital capacity. All showed normal diaphragmatic excursions on fluoroscopy. These patients have been followed for from three to ten months after treatment and all have returned to active military duty.

SUMMARY

Five patients with empyema of varying etiology were treated with aspiration and intrapleural instillation of penicillin. Four patients with acute empyema recovered with little or no pleural thickening and were returned to military duty within three to five months after the onset of illness. One patient with chronic empyema with an acute exacerbation responded to therapy in the acute phase of the disease but eventually required further surgery.

THE MEDICAL TREATMENT OF ACUTE EMPYEMA

REPORT OF FIVE CASES CURED WITH CHEMOTHERAPY AND THORACENTESES

CAPTAIN HERMAN RUDENSKY
MAJOR DAVID H. SPRONG JR.
AND
LIEUTENANT COLONEL CLIFFORD C. WOODS
MEDICAL CORPS, ARMY OF THE UNITED STATES

The addition of sulfonamides and penicillin to our therapeutic armamentarium has changed radically the treatment of many infectious diseases. Treatment of empyema with the newer agents was tried with varying results. According to most authorities, empyema is a disease usually requiring open or continuous closed drainage. Early thoracotomy is recommended in pneumococcic empyemas. Repeated aspirations are ordinarily performed in postpneumonic streptococcic empyemas until the underlying inflammatory process subsides and the purulent exudate becomes thickened, when thoracotomy with rib resection is performed.

The mortality of empyema varies with the etiology, the virulence of the infecting organisms and the resistance of the patient. Moschcowitz's [1] mortality figures for empyema in patients of all ages vary between 18.9 per cent and 45 per cent and he quotes Graham's figure for average mortality in army camps from empyema as 30.2 per cent. It is well known that in anaerobic infections following lung abscesses prognosis is poor. Eloesser [2] writes "Most fatal is the empyema caused by sudden rupture of a lung abscess into a defenseless virgin pleural cavity," and he compares anaerobic empyemas to the fulminating diffuse peritonitis following a ruptured bowel.

Review of the literature by Bufford and Blades [3] shows a reduction in the incidence of empyema following pneumonia from 5 per cent to 1 per cent since the introduction of sulfonamide therapy. However, when empyema does occur after the use of the sulfonamide drugs such cases are more difficult to treat. In their series of 30 cases of unselected empyemas, which occurred during or after sulfonamide treated pneumonias, two deaths occurred, in 2 cases it was necessary to perform secondary drainage operations and in 9 cases there was considerable delay in the expansion of the lung.

The poor results of the treatment of empyema reported in the literature have led to search for other methods of therapy of this serious complication. Keefer,

1. Moschcowitz, cited by Irons, E. E.: Empyema, in Cecil, R. L.: Textbook of Medicine, Philadelphia, W. B. Saunders Company, 1942, p. 983.

3. Bufford, T. H., and Blades, B.: The Influence of Sulfonamide Therapy on Post-Pneumonic Empyema, J. A. M. A. **118**: 950-952 (March 21) 1942.

Blake and their associates[4] were among the first to report the use of penicillin in empyema. We feel that it may be of interest to report 5 consecutive cases of acute empyema of varied etiology, 2 of which followed rupture of lung abscesses into the pleural cavity, treated medically in a somewhat unorthodox manner.

REPORT OF CASES

CASE 1.—A white man aged 26 was admitted Dec. 13, 1943 to the hospital because of a sulfonamide resistant acute gonorrhea complicated by a right epididymitis. On December 20, one week after admission, the patient developed a severe lancinating pain in the right side of his chest, aggravated by deep inspiration and cough. His temperature was 99 F. orally; breath sounds were found to be diminished over the right base and no rales were heard. The patient improved subjectively during the next few days, but on December 23 he became much worse and appeared acutely ill; his temperature rose to 105 F. Signs of diffuse pneumonic involvement in the right lung were confirmed by x-ray examination of the chest, which showed a diffuse stringy infiltration throughout the right lung field. The white blood cell count on December 23 was 13,500, with 92 per cent polymorphonuclears. Sulfadiazine therapy was started the same day. The patient became cyanotic and was placed in an oxygen tent. He expectorated 3 to 4 ounces of bloody sputum daily, and his temperature fluctuated between 101 and 105 F. orally. An x-ray of the chest taken on December 27 showed a "hydropneumothorax," right side, with a fluid level reaching up to the seventh rib posteriorly, which was ascribed to a bronchopleural fistula. Blood culture was negative. The sputum showed hemolytic Streptococcus alpha on smear and culture. The patient's general condition became progressively worse in spite of sulfadiazine therapy, and he appeared to be critically ill. Seventy-four Gm. of sulfadiazine and 8 Gm. of sulfanilamide had been given orally with no apparent effect on the patient's condition.

On Jan. 5, 1944 penicillin therapy was started. On that day the red blood cell count was 3,790,000, with 80 per cent hemoglobin. The white blood cell count was 24,250, with 90 per cent polymorphonuclears and 10 per cent lymphocytes; the sedimentation rate was 52 mm. per hour. Twenty-five thousand units of penicillin was given intramuscularly every three hours. In addition, a thoracentesis was done and 350 cc. of hemorrhagic pus was removed from the right side of the chest and replaced by 100,000 units of penicillin in isotonic solution of sodium chloride. The chest fluid showed many pus cells and red blood cells with diffuse hemolysis, but no bacteria were found on smear or culture. The patient felt somewhat better the next day and his expectoration diminished. Thoracentesis was repeated January 7 and 250 cc. of reddish brown pus was removed from the right side of the thorax and replaced by 100,000 units of penicillin in 125 cc. of saline solution. Transfusion of 500 cc. of blood was given the same day because of the patient's anemia. The temperature became normal January 9 and remained normal, while leukocyte and differential counts were reported to be within normal limits. Aspiration of the right side of the chest was again performed January 13, and it was noted that the exudate changed from reddish brown to green; 210 cc. of pus was withdrawn and replaced by 50,000 units of penicillin in 100 cc. of saline solution. The patient improved and a definite decrease in the amount of sputum, with a loss of its bloody character, was noted.

On January 12 the intramuscular penicillin was decreased to 90,000 units daily and was discontinued altogether on January 17. A total of 1,850,000 units of penicillin had been administered to the patient, of which 250,000 units had been injected locally into the pleural cavity. The final thoracentesis was performed on January 21, when 50 cc. of greenish pus was removed from the chest, with no replacement by penicillin. The patient felt well; dulness on percussion at the right base with diminished breath sounds persisted. X-ray of the chest on January 29 showed increased density at the right base with no fluid level seen. A gradual clearing of the density of the right lung, ascribed to resolving fibrinous pleurisy, was noted on serial x-rays. The sedimentation rate dropped to 10 mm. per hour on February 10. The patient became ambulant early in February; he was given a convalescent furlough March 10 and was discharged to duty two and one-half months later.

CASE 2.—A white man aged 21, a German prisoner of war, gave a history of having been shot on May 4, 1943, with a shell fragment entering the left side of his chest at about the sixth rib posteriorly and leaving the left axilla in the region of the eighth rib. He was treated in a hospital in North Africa for about three months and was sent to the United States about Nov. 8, 1943.

He felt well and had no complaints until Jan. 14, 1944, when he began to have chills, fever, fatigue, weakness and pain in the left side of the chest on deep inspiration. No history of cough, sore throat or dyspnea was elicited.

He was admitted the following day to the station hospital, where on examination his oral temperature was 102 F., pulse rate 96 and respiratory rate 22. Dulness on percussion with suppression of breath sounds in the left lung, more prominent over the left base, was found. No rales were heard and no cyanosis was noted. The blood count on January 16 showed that white cells were 14,650, with 77 per cent polymorphonuclears and 21 per cent lymphocytes. The patient was given sulfadiazine therapy and his temperature subsided in a few days. He became ambulant but had a relapse January 28 with pain in the left side of the chest and rise of temperature to 104 F. X-rays of the chest taken January 17 and January 28 revealed "hydropneumothorax," left side, with fluid about the level of the fourth rib anteriorly and displacement of the heart to the right. Thickening of the pleura along the lateral chest wall was noted, with irregular defects in the left sixth and seventh ribs. Thoracentesis was performed and 30 cc. of thick, foul pus was removed from the left side of the chest. Aspiration of the chest was repeated January 30 and 300 cc. of purulent fluid was withdrawn. Culture of the pleural fluid showed gram positive cocci. The patient was transferred February 6 to this hospital for observation and treatment.

On examination in this hospital the patient appeared to be toxic and emaciated. The temperature fluctuated between 97 and 104.6 F. On physical examination signs of fluid over the right base were found and were confirmed by x-ray examination of the chest. It was felt that the patient had a pyopneumothorax secondary to osteomyelitis of the sixth and seventh ribs. A thoracentesis was performed February 8. One hundred and fifty cc. of thick, greenish, foul pus was withdrawn from the left side of the chest posteriorly and the pleural cavity was irrigated with 1:3,500 of fresh aqueous azochloramid. Sulfadiazine was given at the same time orally. Culture of the pleural fluid showed Proteus vulgaris and Staphylococcus aureus. On February 9 the white blood cells numbered 15,650, with 69 per cent polymorphonuclears and 30 per cent lymphocytes, and the sedimentation rate was 49 mm. per hour. Thoracenteses and irrigations of the pleural cavity with fresh 1:3,500 azochloramid aqueous solution were repeated approximately every other day. From 300 to 400 cc. of pus was removed each time and from 120 to 150 cc. of azochloramid solution was injected into the pleural cavity after each irrigation. The sulfadiazine level was about 9 mg. per hundred cubic centimeters. On this treatment the pus became progressively more fluid and less foul. As the patient's condition improved, aspirations were done less frequently and, on February 24, 100 cc. of clear serous fluid was removed from the left side of the chest and no irrigation with aqueous azochloramid was performed. The fluid gradually absorbed, and on the last x-ray, taken March 9, no fluid in the chest was seen and the left lung was reexpanding. The temperature became normal on February 17 and the patient remained afebrile during his stay in the hospital. A total of 45 Gm. of sulfadiazine was given to the patient. The blood count gradually subsided to normal, and the last sedimentation rate was 10 mm

4. Keefer, C. S.; Blake, F. G.; Lockwood, J. S., and Wood, W. B.: Penicillin in the Treatment of Infections, J. A. M. A. 122:1217-1224 (Aug. 28) 1943.

per hour: The patient had no subjective complaints during his last three weeks of hospitalization, was ambulant, and was transferred to another general hospital for administrative reasons March 15, 1944.

CASE 3.—A white man aged 25, a German war prisoner, was admitted to the station hospital Oct. 17, 1943 with a history of pain in the chest and dyspnea of twenty-four hours' duration; his temperature on admission was 104 F. Physical examination revealed irregular dulness and flatness, bronchial breathing and fine crepitant rales throughout both lower lobes posteriorly. A diagnosis of lobar pneumonia, both lower lobes, was made; x-rays of the chest showed at first a pneumonic process in the left lower lobe, with later spread of pneumonic involvement to the right lower lobe. Sulfadiazine therapy was started October 17 and discontinued October 28, with a total of 84.5 Gm. given. Oxygen therapy was administered at the same time. Sputum examinations showed Staphylococcus aureus, Staphylococcus albus and Friedlander's bacilli on various occasions. The white blood cell count varied from 6,300 to 12,250. The sulfadiazine level fluctuated between 10.8 and 17.8 Gm.

In spite of the intensive sulfadiazine therapy the patient's temperature remained elevated, fluctuating between 98.2 and 103 F. It subsided about October 27, only to rise again to 104 F. two days later, and then fever continued up to 101.4 F. Signs of fluid in the left base were elicited. On serial x-ray films an area of increased density suggestive of pneumonic involvement in the right pericardiac region was noted; in the left lung field a sharply circumscribed mass, radiating from the hilar area and extending about half way to the chest wall, suggestive of encapsulated empyema, was seen. Culture of the sputum was positive for hemolytic Staphylococcus aureus. On Jan. 4, 1944 a thoracentesis was done and 20 cc. of thick pus was withdrawn from the left side of the chest. Staphylococcus albus was isolated on smear and culture from the chest fluid. The patient was transferred January 12 to this hospital for treatment.

On admission to this hospital the patient appeared to be toxic and weak. He had a severe cough and a low grade fever with occasional rise to 102 F.; on physical examination signs of fluid at the left base were elicited. A thoracentesis was done and 400 cc. of sanguineous, purulent fluid was removed from the left side of the chest and 50,000 units of penicillin in 200 cc. of saline solution was injected into the empyema cavity. Smear and culture of the fluid showed Staphylococcus aureus. An x-ray film of chest taken the next day showed an increase in density in the left side, with apparent rupture of the encapsulated empyema into the pleural cavity. The blood count was essentially normal. On January 19 a second thoracentesis was done and 175 cc. of hemorrhagic purulent fluid was removed and replaced by 32,500 units of penicillin in 130 cc. of saline solution. Staphylococcus albus was isolated from this fluid on smear and culture. On January 28 a third thoracentesis was done and 100 cc. of pus was withdrawn and 25,000 units of penicillin in 100 cc. of saline solution was injected into the empyema cavity. The fluid withdrawn proved to be sterile on smear and culture. An x-ray film of the chest on January 26 showed an area of increased density to be smaller, with a small localized pyopneumothorax near the left side of the mediastinum, with fluid level at the anterior end of the third left rib. The patient's temperature dropped to normal January 28 and remained normal. On February 15 x-ray examination of the chest showed only slight thickening of the pleura in the left mediastinal region. The localized area of density and fluid level had apparently disappeared; obliteration of the left costophrenic sinus was noted; the right lung was apparently clear. The patient improved subjectively and had very few complaints except for occasional pains in the left side of chest. A total of 107,500 units of penicillin had been injected into the pleural cavity during the three thoracenteses. No other specific therapy was given during his stay at this hospital. The patient was discharged from the hospital for administrative reasons in the beginning of March 1944.

CASE 4.—A white man aged 25 was admitted to the station hospital Feb. 21, 1944 because of an upper respiratory infection, which was followed by a diffuse pemphiginous eruption consisting of vesicles and bullae, varying in size up to half a dollar (30 mm.) and involving the mucosa of the oral cavity and conjunctiva; the eruption rapidly spread and covered most of the body. The temperature fluctuated between 99 and 106 F. The patient was treated with 440,000 units of penicillin administered between February 27 and March 5. By March 11 the bullae disappeared with resultant macular stains and persistent fetor oris. On March 13 the patient began to complain of pain in the lower right side of the chest; his temperature rose to 103 F. Breath sounds were diminished over the right base and x-ray examination of the chest showed pneumonic involvement in the right lower lobe. Penicillin therapy was started again; 5,000 units was administered intramuscularly every two hours and discontinued on March 16. A total of 150,000 units was given in three days. A diagnosis of lung abscess, right side, confirmed by x-ray examination of the chest, was made on March 20. Rapid progressive increase in the abscess was noted, and penicillin therapy was renewed March 21 with about 120,000 units given by March 23, at which time it was discontinued. The patient was expectorating about 1 pint of foul, bloody mucopus daily. He became rapidly worse, he had chills and his temperature was fluctuating between 98 and 105.6 F. orally. A total of about 710,000 units of penicillin was given during the three periods of treatment in the station hospital. Because of a progression of the pathologic condition the patient was transferred to this hospital on March 30, 1944.

On admission to this hospital the patient appeared to be toxic, somewhat irrational and critically ill; his temperature was 104.4 F. On physical examination signs of fluid over the right base and of acute diffuse bronchitis were elicited. The white blood cells numbered 24,000, with 80 per cent polymorphonuclears; the sedimentation rate was 62 mm. per hour; blood culture was negative. X-ray examination of the chest showed diffuse irregular density throughout the middle and lower lobes of the right lung; density in the right base was noted, with a shifting fluid level in the seventh interspace posteriorly, reaching the chest wall laterally. The impression from clinical and x-ray findings was lung abscess, with rupture into the pleural cavity and resulting empyema at the right base.

The patient was placed in an oxygen tent and on postural drainage. Sulfadiazine therapy was started on admission, supplemented April 1 by 25,000 units of penicillin intramuscularly every three hours because of his presumably mixed infection. He expectorated about 6 ounces of bloody, greenish sputum daily, at times foul in character. Sputum examination showed alpha streptococci, Staphylococcus aureus and Neisseria catarrhalis.

A thoracentesis was performed April 2, and 250 cc. of sanguineous, foul pus was removed and replaced by 50,000 units of penicillin in isotonic solution of sodium chloride. Laboratory examination of the purulent exudate showed nonhemolytic streptococci on culture; the pleural fluid sugar was too low to be determined colorimetrically; the white blood cells numbered 33,000, with 86 per cent polymorphonuclears and diffuse hemolysis of red blood cells. Thoracentesis was repeated two days later and 210 cc. of greenish pus was removed from the right pleural cavity. The pleural fluid was not as foul as it was the first time, and it was negative on smear and culture for pathogenic micro-organisms, as were succeeding pleural fluids; 100,000 units of penicillin in 100 cc. of isotonic solution of sodium chloride was injected into the pleural cavity. A transfusion of 500 cc. of blood was given the same day because the patient's hemoglobin had dropped to 52 per cent. The patient continued to improve and his temperature subsided to 99-101 F. Thoracentesis was repeated April 6, with 70 cc. of greenish pus removed and replaced by 200,000 units of penicillin intrapleurally. His temperature subsided to normal April 7 and remained normal. The expectoration decreased gradually to 1 to 2 ounces daily and became greenish instead of bloody and lost its foul odor. On April 7 the red blood cells numbered 3,520,000, hemoglobin 78 per cent Sahli, white

blood cells 7,600, with essentially normal differential count. Another thoracentesis was performed April 10 and 70 cc. of greenish pus was removed and replaced by 40,000 units of penicillin in isotonic solution of sodium chloride; the same day the penicillin dosage was cut to 90,000 units intramuscularly and sulfadiazine was diminished to 4 Gm. daily. The blood sulfadiazine level fluctuated between 5.3 and 8 mg. per hundred cubic centimeters. The patient continued to improve; cough and expectoration disappeared and his appetite was good.

On April 17 the last thoracentesis was performed and 20 cc. of yellowish-brown seropurulent fluid was removed from a small empyema pocket between the eighth and ninth ribs posteriorly. The cavity was irrigated with saline solution and 8,000 units of penicillin was instilled intrapleurally. Sulfadiazine therapy was discontinued April 14, while penicillin was discontinued April 17. A total of 78 Gm. of sulfadiazine was administered; 2,445,000 units of penicillin was given to the patient intramuscularly and 398,000 units into the pleural cavity. The patient improved steadily; he gained about 35 pounds (16 Kg.) during his stay in the hospital. Serial x-ray films of the chest showed thickening of the right pleura and obliteration of the right costophrenic sinus, with progressive resolution in the pleural pathologic condition. The last x-ray examination of the chest showed elevation of the right diaphragm, but the right lower lobe appeared to be clear otherwise. The patient became ambulatory about April 25. He became progressively more active but because of a residual persistent bronchitis was discharged from the Army the beginning of August 1944.

CASE 5.—A white man aged 30 gave a history of chronic cough for about three years. He had had malaria in September 1942, with recurrence in June 1943. About March 28, 1944 he began to have severe pain in the left side of his chest, aggravated by deep inspiration; he was admitted to the station hospital April 3, 1944.

On admission his temperature was 101.4 F. orally. Physical examination of the chest revealed pneumonic involvement of the left lower lobe. The white blood cells numbered 14,100, with 84 per cent polymorphonuclears. The sedimentation rate was 55 mm. per hour. The sputum was negative for pneumococci and tubercle bacilli. The x-ray film of the chest taken April 4 showed an elliptic area of decreased density suggestive of cavity formation with fluid level, probably lung abscess, in the left lung field. The patient was placed in an oxygen tent, and sulfadiazine was given for three days, with the blood level reaching 10.2 mg. per hundred cubic centimeters. As the patient did not improve, sulfadiazine therapy was replaced by penicillin April 6; 25,000 units was given intramuscularly every three hours. An x-ray film of the chest taken April 8 showed an increase in pneumonic involvement and two areas of increased density suggestive of a double lung abscess on the left side. A thoracentesis was attempted, but no fluid was obtained. Because of rapid progression of the pulmonary lesions in spite of intensive therapy, the patient was transferred to this hospital April 8 for further treatment and observation.

On admission to this hospital the patient appeared to be seriously sick. His face was flushed and he reacted sluggishly. His temperature was 102 F. on admission and fluctuated between 98.4 and 103 F. rectally; the pulse rate was 120. Signs of fluid in the left base up to about the seventh rib posteriorly and some crepitant rales above that area were noted; many sibilant rales were heard throughout the right side of the chest. The red blood cells numbered 4,090,000, with hemoglobin 76 per cent Sahli and white blood cells 17,550, with 83 per cent polymorphonuclears. Smear and culture of the sputum showed Staphylococcus aureus and alpha streptococci; blood culture was negative. X-ray examination of the chest showed diffuse density in the left base, with a definite fluid level extending to the left axilla in the region of the seventh rib. Because of clinical and x-ray findings, it was felt that the patient had a double lung abscess which had fused and ruptured into the pleural cavity with formation of an empyema.

Because of the severity of the disease and probable mixed infection, the patient was treated with a combination of sulfadiazine and penicillin. Sulfadiazine 4 Gm. followed by 1 Gm. every four hours, with an equal amount of sodium bicarbonate, was administered orally; 25,000 units of penicillin was given intramuscularly every three hours. The patient was placed on postural drainage and he expectorated from 5 to 6 ounces of yellowish green sputum daily. A thoracentesis was performed April 10 and 75 cc. of greenish foul pus was removed from the left pleural cavity and replaced by 60,000 units of penicillin in isotonic solution of sodium chloride. Smear and culture of the pleural fluid showed gram positive cocci in chains, gram positive rods and gram negative rods. On April 12 another thoracentesis was done and 250 cc. of greenish yellow pus was removed from the left side of the chest and replaced by 100,000 units of penicillin in isotonic solution of sodium chloride.

Thoracenteses were repeated about every other day, with removal of greenish yellow pus varying in amount from 320 cc., April 17, to 70 cc. on April 26. The purulent fluid was replaced by 50,000 to 100,000 units of penicillin each time. Pus became gradually less foul until it lost its odor completely; cultures and smears of pleural fluids were persistently negative for pathogenic micro-organisms following the first positive smear and culture of pleural fluid. On April 17 416,000 white blood cells per cubic millimeter were reported on examination of the chest fluid, with 92 per cent polymorphonuclears and 8 per cent lymphocytes. Blood cell and differential count showed a mild leukocytosis with hemoglobin 94 per cent Sahli. The blood sulfadiazine level varied between 3.9 and 10.2 mg. per hundred cubic centimeters. Blood and stool cultures were negative for parasites. On May 6 the last thoracentesis was performed and 30 cc. of yellowish green purulent odorless fluid was withdrawn from the pleural cavity and replaced by 10,000 units of penicillin in saline solution. The sedimentation rate was reported as 46 mm. per hour on April 25, 23 mm. per hour on May 8, 7 mm. per hour on May 24 and 4 mm. per hour on July 8.

A total of 79 Gm. of sulfadiazine was given orally between April 8 and April 22; 2,450,000 units of penicillin was given intramuscularly and 560,000 units was injected into the pleural cavity. Serial x-rays of the chest showed progressive diminution in pleural pathologic change in the left side of the chest, and the last x-ray of the chest, taken July 8, showed a slight residual fibrosis throughout the left lower lobe, with elevation of the left diaphragm and partial obliteration of the left costophrenic sinus.

The patient has been feeling well, although he has had a cough; on examination, some sibilant and sonorous rales were heard throughout the chest, ascribed to an underlying allergic bronchitis. He was given a convalescent furlough June 26 and was sent for rehabilitation July 13. The general condition of the patient is good at the time of this report.

COMMENT

Five unselected patients with acute empyema, all seriously sick when first seen, were treated medically. Three of the cases were putrid empyemas, 2 of which followed ruptured lung abscesses with bronchopleural fistulas. We were impressed by the severity of the infection as shown by the hemorrhagic type of the purulent exudate in 4 of the cases, and the anaerobic type of infection in cases 2, 4 and 5, as evidenced by the foul odor of the pus. Lyons [5] has reported 4 cases of lung abscess, 2 of which were putrid and were not benefited by penicillin therapy, and 2 pyogenic cases in which improvement occurred after treatment with penicillin; 1 patient with hemolytic streptococcic empyema died in spite of treatment with penicillin. We feel that the cures in our 2 cases of lung abscess were probably due to the rupture into the pleural cavity, where the infection was more accessible to the effect of the therapeutic agents used.

5. Lyons, C.: Penicillin Therapy of Surgical Infections in the United States Army, J. A. M. A. 123: 1007-1018 (Dec. 18) 1943.

Keefer, Blake and their associates [4] reported 5 cases of postpneumonic empyemas, 2 of which improved after penicillin treatment; in 7 of 9 of their cases of staphylococcic empyema improvement or recovery followed treatment with the same therapeutic agent. Two of 3 cases of lung abscesses were treated by the same authors with penicillin; they reported two cures and one death, in spite of treatment.

In putrid empyemas repeated thoracenteses are considered definitely contraindicated by some writers. Maier and Grace [6] felt that aspiration in such cases was associated with considerable danger of infection of the chest wall. Four of their patients developed phlegmonous infections of the thoracic wall, and 2 of their patients, who were subjected to aspiration twice before thoracotomy, died. These authors concluded, therefore, that open thoracotomy with rib resection was the procedure of choice as soon as the diagnosis of putrid empyema was confirmed by diagnostic aspiration.

In our experience, a combination of sulfadiazine and penicillin given at the same time and associated with repeated aspirations of purulent exudate and its replacement by penicillin proved to be beneficial in cases of mixed infections, aerobic or anaerobic. No untoward effects were noted in putrid empyemas from repeated thoracenteses. We fully agree with Keefer, Blake and their associates that it is impossible at present to sterilize empyema cavities by the parenteral use of penicillin alone. Neither penicillin nor sulfadiazine, nor the combination of the two, can take the place of good medical judgment in replacing accumulations of pus with penicillin or azochloramid.

We were favorably impressed with the effect of combined sulfadiazine and azochloramid therapy in case 2, from the pleural fluid in which Proteus vulgaris and Staphylococcus aureus were isolated. It may be well worth further trial in cases not responding to penicillin therapy.

The importance of chemotherapy and antibiotics in treatment of infectious diseases is increasing steadily. We fully appreciate that the series of empyemas presented is too small to serve as the basis for definite conclusions, but the results are so encouraging that further trial with medical treatment of empyema as outlined is fully justified. The treatment of empyema, however, continues to be both a medical and a surgical problem.

SUMMARY

1. Two cases of putrid empyema due to ruptured lung abscesses were treated with combination of sulfadiazine and penicillin. Penicillin was administered intramuscularly and intrapleurally following repeated thoracenteses. Treatment resulted in rapid improvement and cure.

2. One case of postpneumonic empyema was treated with penicillin intramuscularly and intrapleurally, following repeated thoracenteses, with rapid improvement.

3. One case of postpneumonic empyema, apparently caused by Staphylococcus aureus and Staphylococcus albus, was treated with penicillin locally, following aspirations of pus, with progressive improvement and cure.

4. One case of empyema, apparently caused by Staphylococcus aureus and Proteus vulgaris, was treated with sulfadiazine orally, repeated thoracenteses and azochloramid intrapleurally, with rapid cure.

ADDENDUM

Since completion of this paper, one of us (H. R.) has successfully treated medically 3 more cases of empyema. Sulfadiazine orally and azochloramid instilled locally following each of repeated thoracenteses were used in 1 case. In 2 others, 1 complicating staphylococcic septicemia, local and parenteral penicillin was employed in addition to oral sulfadiazine and repeated aspirations of empyema cavities.

THE VALUE OF PENICILLIN IN THE TREATMENT OF EMPYEMA

JOHN WINSLOW HIRSHFELD, M.D.
C. W. BUGGS, PH.D.
WILLIAM E. ABBOTT, M.D.
AND
MATTHEW A. PILLING, M.D.

DETROIT

Penicillin is almost nontoxic for man, yet it exerts a powerful antibacterial action against a wide variety of micro-organisms. Unlike the sulfonamides, penicillin is not inhibited by pus or other products of tissue destruction.[1] When given intravenously or intramuscularly, it penetrates poorly into collections of pus, but if it is injected directly into an abscess it remains there for some time and may be found in considerable concentration as long as twenty-four to forty-eight hours after its injection.[2] These unusual properties of penicillin have led some workers [3] to treat empyema by aspiration of the pus, followed by instillation of penicillin. Theoretically, if this form of treatment is to be successful, the following conditions should prevail:

1. The causative bacteria must be susceptible to penicillin.
2. It must be possible for penicillin instilled in the empyema to contact all of the bacteria. Some empyemas are loculated so that it is impossible to reach all of the pockets with an aspirating needle.
3. The cavity must not contain pieces of necrotic lung or large clots of fibrin. Many empyemas of long standing, especially those caused by pneumococci, contain clots of fibrin several inches in diameter. An occasional empyema contains a piece of necrotic lung in the interstices of which bacteria are protected. Penicillin will not sterilize an empyema until these fibrin clots and pieces of necrotic lung are removed.

This study was supported by the Theodore A. McGraw Fund.

4. The anatomic conditions such as bronchial fistulas that cause constant reinfection of the cavity and allow the penicillin to escape must not be present. Bronchial fistulas, present more often than is generally realized, not only permit constant contamination of the cavity by organisms from the mouth but make it impossible to keep penicillin in the empyema.

5. The lung must be capable of reexpanding. Since reexpansion of the lung is the means by which empyema is cured it is obvious that, if the lung is not capable of reexpanding, aspiration of pus and instillation of penicillin will not suffice to heal the lesion.

There is no doubt that penicillin when properly used will obviate the need of surgical drainage in certain cases of empyema. Those responding to penicillin are chiefly the cases that have been detected relatively early when the pus is still thin and those in which none of the complications described are present. There is also no doubt however that, even when the complications described are present, penicillin can be of considerable aid as an adjunct to surgery. By means of penicillin and aspiration a large empyema can often be transformed into a small one that the lung can obliterate more quickly after rib resection. It is also possible to tide a critically ill patient over a period during which surgical intervention is hazardous. However, if the empyema is not bacteriologically and anatomically such that it will respond to penicillin therapy, to persist with aspiration of pus and instillation of penicillin is useless. An empyema is cured by expansion of the lung. Once the pleura becomes so thick that the lung cannot reexpand, an empyema cannot be cured by any means short of an operation designed to move the chest wall in to meet the lung. Such a procedure is serious and deforming and often must be done in stages. Drainage of an empyema by resecting a small section of rib under local anesthesia is such a trivial procedure compared to the operation for obliteration of chronic empyema that one is not justified in risking the possibility of having to do the latter in hopes of avoiding the former. It is rational then to treat an empyema by aspiration of pus and instillation of penicillin as long as rapid improvement is being made. If the patient becomes afebrile and the fluid decreases in amount, becomes sterile on culture and resembles the penicillin that was injected, satisfactory progress is being made. However, if the patient has a persistent fever, if the pus continues to accumulate and if the cavity fails to decrease rapidly in size, surgical drainage should be accomplished without further temporizing.

To summarize, use penicillin:

1. To cure small empyemas without loculation, lung sequestrums or bronchial fistulas.
2. To make large empyemas smaller.
3. To tide over a critically ill patient until he can be operated on safely.

The following cases, selected from those that have been treated with penicillin at the City of Detroit Receiving Hospital, illustrate these points:

REPORT OF CASES

CASE 1.—C. M., a Negro aged 39, was admitted on April 15, 1944 with multiple stab wounds, one of which involved the left chest wall, the diaphragm and the stomach. Because the patient had consumed a large meal and considerable alcohol shortly before injury, his stomach was full and there was extensive soiling of the peritoneum. The wounds were repaired, and the chest and abdomen were closed without drainage. Postoperatively a pleural effusion developed on the left. On the fifth day following injury the abdominal wound disrupted. This was resutured under general anesthesia. The temperature, which had been elevated from the time of the first operation, remained elevated. On May 8, twenty-two days after admission, 60 cc. of pus was obtained from the left pleural cavity. Nonhemolytic streptococci and unidentified anaerobic cocci were recovered from the pus. The streptococci were sensitive to 0.04 unit per cubic centimeter of penicillin in vitro; the sensitivity of the anaerobic cocci to penicillin was not tested. Beginning on May 12 the empyema was aspirated daily and each aspiration followed by the instillation of 50,000 units of sodium penicillin in a few cubic centimeters of saline solution. The pus maintained its purulent character but gradually decreased in amount. On June 10, only 1 cc. could be obtained, and no further aspirations were done. The temperature became normal after thirteen days of therapy, and the patient has remained well to date.

Cultures of the pus were as follows:

May 8 and 13, nonhemolytic streptococci and unidentified anaerobic cocci.

May 14, aerobic gram positive spore forming bacilli.

May 17 and 25, nonhemolytic streptococci and unidentified anaerobic cocci.

June 4 and 9, no growth.

In this instance the empyema was small, was not loculated, was easily aspirated and was caused by organisms susceptible to penicillin. Aspiration of the pus followed by instillation of pencillin was therefore sufficient to cure the lesion. However, it required twenty-three days to sterilize the empyema and thirty days of therapy in spite of the sensitivity of the streptococcus to penicillin. The morbidity was about equal to that which would have accompanied surgical drainage; hence, while the treatment was successful, it had no great advantage over surgery. If, on the seventeenth day, it had been decided to do a rib resection because the pus had not yet been sterilized, the period of morbidity would have been longer than thirty days. Often during the treatment of empyema with penicillin it is difficult to decide whether the therapy is effective. Sometimes the patient improves clinically but the pus does not become sterile. At other times the pus becomes sterile but the patient remains febrile. Under such circumstances it is difficult to decide whether persistence in the treatment will result in a cure or whether rib resection will ultimately be necessary. If one resorts to rib resection after three weeks of penicillin therapy, the period of morbidity is prolonged. However, if one persists for many more weeks, one is risking the occurrence of chronic empyema if the treatment is not effective. The next case illustrates these difficulties:

CASE 2.—J. B., a white man aged 51, was admitted on Feb. 18, 1944 with type II pneumococcic pneumonia involving the right lower lobe. Treatment with sulfamerazine resulted in a slight improvement, but the patient's temperature remained elevated. On March 1 250 cc. of thick pus yielding a type II pneumococcus was aspirated from the right pleural cavity. Following removal of the pus, the patient's temperature fell to normal and remained normal until March 6, when it rose again to 102-103 F. On March 6 the empyema was aspirated and 50,000 units of penicillin was instilled into the cavity. Aspiration and instillation were repeated twice daily for three days and then once daily for sixteen more days until March 25. Cultures of the pus during this period were as follows:

March 6 and 7, type II pneumococci.

March 8, 9, 10, 12, 13, 14 and 15, sterile.

March 24, type II pneumococci.

Although the pus appeared to become sterile shortly after the instillation of penicillin, the patient did not improve clinically. His temperature remained elevated and pus continued to

accumulate. In spite of the large amount of pus that was present, it was often difficult to withdraw much with a syringe because, as was subsequently shown at operation, large clots of fibrin blocked the needle. Since the patient failed to improve, it was decided to supplement the local instillation of penicillin with penicillin given intramuscularly. From March 14 to March 25 the patient received 10,000 units of penicillin intramuscularly every two hours in addition to the daily injection of 50,000 units in the empyema. During this regimen his temperature approached but did not reach normal, and the pus continued to accumulate. On March 24, after six negative cultures, pneumococci were again recovered from the pus. Accordingly it was decided to do a rib resection. Operation on March 28 disclosed a large cavity containing almost a liter of thick pus in which were many huge clots of fibrin. The pus obtained at operation was sterile. The character of the pus and the presence of fibrin apparently had prevented aspiration of the cavity.

This patient required rib resection after three weeks of very intensive penicillin therapy. The cavity was unilocular and easily accessible but contained so much thick material that it was impossible to aspirate the pus properly. The probable location of the pneumococci in the protected meshes of the fibrin was perhaps responsible for the positive culture on March 24, after twenty days of therapy, and for the continued accumulation of pus. Sixty-five days were required for healing. In this case reliance on penicillin prolonged rather than shortened the period of morbidity.

Case 3 illustrates the improvement that penicillin therapy can bring about in putrid empyema, but it at the same time illustrates one of the dangers of this form of treatment. The patient, feeling so much better because of the therapy, refused operation and left the hospital while viable streptococci could still be recovered from the pus in his chest. He may well develop chronic empyema.

CASE 3.—H. W., a white man aged 64, was admitted complaining of pain in his right chest of three days' duration. He had signs of right lower lobe pneumonia, but no pneumococci were found in the sputum. His temperature ranged between 100 and 102 F. He developed fluid in the right pleural cavity, and on Oct. 19, 1944 the chest was aspirated and a large quantity of pus obtained. Alpha hemolytic streptococci were recovered on culture. Unfortunately no anaerobic cultures were made, but the foul character of the pus indicated that anaerobes must have been present. There was some delay in obtaining penicillin, so the chest was not aspirated again until October 25, when 1,500 cc. of very foul pus resembling pea soup in appearance was obtained. Following the aspiration, 50,000 units of penicillin in about 80 cc. of saline solution was instilled in the empyema. On October 27 550 cc. of pus, which was no longer foul, was obtained. The temperature fell to normal on this day and remained normal for the rest of the hospital stay. Aspiration of pus and instillation of 50,000 units of penicillin was done daily until November 9. Although the fluid decreased in amount, only about 100 cc. being obtained the last few times it remained purulent and, except for an isolated sterile culture on November 2, always contained viable streptococci. On November 9, after two weeks of therapy, rib resection was advised, but the patient felt so well that he refused operation. Penicillin therapy was stopped. Aspiration on November 23 yielded 50 cc. of thin, brown, odorless fluid from which streptococci were grown on culture. Aspiration on December 4 yielded only 4 cc. of fluid, but on December 7 30 cc. was obtained. X-rays still revealed an encapsulated empyema.

On December 8 the patient left the hospital against advice. Although the empyema may in this case go on to resolution, the patient left the hospital with fluid which still contained streptococci in his pleural space. It is well known that such lesions may remain quiescent for months or even years and then flare up. We are inclined to believe, therefore, that eventually the patient will develop chronic empyema. There is no doubt that penicillin improved this patient's condition by reducing the size of the empyema and by killing the anaerobes, which were apparently originally present in the pus. If rib resection had been done when his chest contained 1,500 cc. of foul pus, a long time would have been required for reexpansion of the lung. However, if rib resection had been done after reduction in the size of the empyema cavity by one to two weeks of penicillin therapy, expansion would have occurred rapidly. Used to reduce the size of an empyema before operation, penicillin is of considerable value.

CASE 4.—O. H., a white man aged 47, was admitted on Oct. 9, 1944 with multiple stab wounds, one of which had entered the peritoneal cavity, lacerating the omentum and the liver. The patient had consumed sufficient alcohol to make him very uncooperative, and it was necessary to use general anesthesia in order to keep him quiet enough to permit repair of his wounds. Postoperatively he developed pleural effusion on the right. On October 20 aspiration of the right pleural cavity yielded 1,100 cc. of thin, brown fluid. No culture was made. The patient's temperature at this time was 101-102 F. Treatment with sulfadiazine was begun, the initial dose of 4 Gm. being followed by 1 Gm. every four hours. The temperature declined over a three days period to 99-100 F., where it remained until November 1, when the chest was again aspirated. Only a small amount of very thick pus was obtained. Type VIII and type XV pneumococci were recovered from the pus; 50,000 units of penicillin was injected into the empyema. Aspiration followed by injection of 50,000 units of penicillin was repeated daily until November 6, The cultures became negative after twenty-four hours of therapy. The temperature also fell to normal after twenty-four hours of therapy and remained normal. The patient has remained well to date.

This patient was treated successfully by only a few injections of penicillin. The good response in this case, as in the following one, was probably due to the small size of the empyema and the susceptibility of the organisms to penicillin.

CASE 5.—E. S., a white man aged 42, was admitted on March 28, 1944 for treatment of peritonitis caused by perforation of a peptic ulcer three days previously. Although his temperature was only 99-100.6 F. the patient was critically ill. On April 5 his temperature rose to 103 F. and he developed signs of a subdiaphragmatic abscess. On April 8 the posterior subdiaphragmatic area was explored; no definite pus was encountered, but the entire area contained fresh fibrinous adhesions between which were collections of clear fluid. There was no improvement following the operation, and by April 12 pleural effusion had developed. The temperature remained elevated. Fluid was aspirated from the right chest on April 14, but it clotted rapidly and no cultures were made. On April 17 the anterior subdiaphragmatic space was opened and a large abscess drained; beta hemolytic streptococci and Escherichia coli were recovered. Following drainage the patient's condition improved somewhat, but his temperature continued to rise and it was obvious that another collection of pus was present. On May 1 200 cc. of thin pus was aspirated from the right pleural cavity. Beta hemolytic streptococci, which were sensitive to 0.01 unit of penicillin per cubic centimeter, were recovered from the pus. On May 5 aspiration was repeated and 40,000 units of penicillin was instilled in the cavity. Aspiration and instillation were repeated daily for three days, and then 50,000 units of penicillin was injected daily for four days. The pus became sterile after the first twenty-four hours of treatment and decreased rapidly in amount. The last attempt at aspiration on May 15 yielded only a few cubic centimeters of fluid. The empyema has not recurred.

CASE 6.—V. B., a white woman aged 26, admitted on May 15, 1944, had had a pelvic operation three weeks prior to admission at another hospital, following which some sort of pulmonary complication occurred. This had not subsided, and she was acutely ill when she was admitted to the Detroit Receiving Hospital. On May 17 200 cc. of very foul, green pus was aspirated from the right pleural cavity. An anaerobic nonhemolytic streptococcus and alpha hemolytic streptococci were cultured from the pus. On May 20 the patient suddenly became critically ill. She was cyanotic and dyspneic and on physical examination exhibited not only signs of hydropneumothorax on the right but also numerous moist rales throughout the left lung. Her temperature was 104 F. It was believed that she had developed a bronchopleural fistula and had soiled the left lung with pus from the empyema. The empyema was completely aspirated and 50,000 units of penicillin was injected. Aspiration and instillation were repeated daily for thirteen days and the patient was also given 10,000 units of penicillin intramuscularly every hour for twenty-two days in order to control the soiling of the left lung. The patient's general condition improved slowly. Twenty-four hours after the onset of therapy the temperature fell to 100-101 F., where it remained for nine days before leveling off at normal, 100 F. The pus that was aspirated decreased steadily in quantity, lost its foul odor and changed to a thin brown fluid. The cultures were as follows:

May 19 and 20, 1944 alpha hemolytic streptococci and anaerobic nonhemolytic streptococci.

May 23, aerobic gram positive spore forming bacilli.

May 24, 25 and 27, sterile.

Although the empyema decreased in size, the bronchopleural fistula prevented the lung from reexpanding completely, and the patient continued to have a low grade fever. On May 8 a rib resection was done. This disclosed a small empyema into which there were several bronchial openings. Cultures from the walls of the cavity yielded anaerobic nonhemolytic streptococci.

In this instance penicillin therapy apparently saved the life of a critically ill patient. The penicillin that was given intramuscularly controlled the infection in the left lung, while further soiling was prevented by a combination of aspiration of the empyema and instillation of penicillin. By these means the patient's condition was improved and the size of the empyema was greatly reduced. When rib resection was finally done it was a simple procedure in a patient who was in good condition.

The next case illustrates a similar but more complicated problem:

CASE 7.—E. S., a white man aged 39, was admitted on Oct. 21, 1944 with type II pneumococcic pneumonia involving the right lower and middle lobes. He had been ill at home for seven days. At the time of admission his temperature was 105 F. and he was comatose. Because of his serious condition he was treated with penicillin, receiving an initial dose of 30,000 units intravenously and 20,000 units intramuscularly. This was followed by 15,000 units intramuscularly every three hours for fourteen days. Over the course of a week the temperature gradually fell to levels of 99-100 F. and considerable improvement had occurred. On November 4, when penicillin was discontinued, his temperature rose abruptly to 102 F. and remained at about this level until November 10, when it again fell almost to normal. In spite of the lowered temperature he continued to show anorexia, lethargy, a cough and weakness. During the next few weeks he improved slightly but had periods with a relatively normal temperature alternated with periods of fever. Because of the persistent signs of infection, consolidation of the right lower lobe, the absence of demonstrable empyema and x-ray evidence suggestive of multiple abscess formation, it was decided to reinstitute systemic penicillin therapy. On November 29 an initial dose of 20,000 units was given intramuscularly followed by 15,000 units every three hours. Penicillin was continued until December 17. On December 2 fluid was detected in the right pleural space and aspiration yielded 30 cc. of thick pus from which Staphylococcus aureus was recovered. Following aspiration 50,000 units of penicillin was instilled into the empyema. This procedure was repeated daily until December 11. Considerable difficulty was encountered in aspirating the empyema. At times 20 to 30 cc. of pus was obtained, while at other times nothing could be aspirated. It was apparent that a bronchial fistula existed, since the patient coughed and expectorated some of the solution each time it was injected.

In spite of systemic administration and the instillation of penicillin directly into the empyema, the patient failed to improve, and on December 12 a rib resection was done. The findings at operation were adequate to explain both the difficulties encountered at aspiration and the failure of the patient to improve. The empyema was fairly large, extending from the posterior axillary line to the paravertebral region and from the seventh to the ninth rib. There were several bronchial fistulas opening into the cavity, which contained a piece of necrotic lung about 3 inches in diameter. Traversing the cavity were several large vessels that could have given rise to a fatal hemorrhage at any time. Aspiration had been difficult for two reasons: (1) bronchial fistulas had provided sufficient drainage to prevent the accumulation of any great quantity of pus; (2) a lung sequestrum had covered the needle, making it impossible to aspirate either air or pus through it. Under such circumstances penicillin therapy could not have been expected to cure the lesion. Furthermore, the constant hazard of severe hemorrhage from the vessels traversing the cavity made it dangerous to delay surgical treatment.

The next case demonstrates the seriousness of delaying surgical drainage when large vessels traverse an abscess cavity.

CASE 8.—E. B., a Negro woman aged 23, admitted on Oct. 29, 1943 with an abscess near the base of the left upper lobe, had had a tonsillectomy six weeks previously. Pleural effusion developed; the patient became extremely dyspneic and had frequent small hemoptyses. On November 9 200 cc. of foul, thin, purulent fluid was aspirated from the left pleural cavity. Anaerobic hemolytic streptococci, anaerobic nonhemolytic streptococci and several unidentified anaerobic bacilli and cocci were recovered from the pus. Penicillin therapy was initiated on November 10. Ten thousand units was injected into the empyema daily, and 50,000 units was given intramuscularly every hour for twelve hours. The dose was then reduced to 10,000 units intramuscularly every hour. This was continued for fifteen days.

Improvement was slow but progressive. The amount of sputum decreased, the patient was able to dispense with the oxygen tent, and her appetite improved. The foul odor promptly disappeared from the fluid aspirated from the chest, and anaerobic streptococci were not recovered from it after the fourth day of therapy. Because of a shortage of penicillin the dose was decreased on the morning of the twelfth day to 5,000 units per hour. On November 22, the thirteenth day of treatment, only a small amount of sterile fluid was obtained on aspiration, and the temperature became normal. On November 23, the fourteenth day, it was necessary to decrease the dose again, and from this time until her death she received only 2,500 units every two hours. On November 25, the sixteenth day, she felt worse, and her temperature rose. That evening she had a fatal hemoptysis. At autopsy the empyema was found to be completely obliterated. An abscess about 1 inch in diameter was present in the left upper lobe and was surrounded by considerable consolidated lung containing many small abscesses. A large eroded vessel traversed the cavity.

This case might be considered a success so far as treatment of the empyema was concerned, and it illustrates the remarkable improvement that can be obtained in critically ill patients through the use of penicillin. It also illustrates, however, that penicillin cannot be

expected to correct certain anatomic changes; when these are present, surgical intervention should be prompt.

CASE 9.—G. G., a white man aged 63, who had been a tramp all his life, admitted to the hospital on Nov. 15, 1944 with a massive pleural effusion, had been ill for over a month, but he could not give a satisfactory account of his illness. He was very malnourished. On November 20 1,650 cc. of rather thin, foul, purulent fluid was aspirated from the right chest. More fluid was present, but the patient became so weak that aspiration had to be discontinued. Cultures of the fluid yielded beta hemolytic streptococci. On November 22 930 cc. of foul pus was aspirated and 50,000 units of penicillin instilled in the empyema. Aspiration and instillation were repeated daily for three days and then every other day for twenty-three days. The amount of fluid that could be aspirated decreased from 1,440 to 250 cc., and the cultures became negative on the tenth day of therapy. The patient did not improve a great deal, however. He continued to have a temperature of 99 to 100 F., his appetite was poor and he developed diarrhea. No cause for the diarrhea could be found.

Because of the persistent accumulation of pus after twenty-three days of therapy, failure of the cavity to decrease significantly in size during the last week of therapy and the patient's persistent poor condition and low grade fever, rib resection was done under local anesthesia on December 16. The cavity held about 250 cc. and was unilocular. Following operation beta hemolytic streptococci were again recovered from the empyema. The patient's course after operation was progressively downhill, and he died on Jan. 6, 1945. Death was due to multiple pulmonary infarcts. The empyema itself was progressing well.

This patient was in extremely poor condition when he was admitted to the hospital, and the delay of seven days between admission and the onset of therapy did not improve it. Whether the outcome would have been different if treatment had been instituted earlier or if surgical drainage had been done is not pertinent to this discussion. The point is that in an empyema of this size and duration twenty-three days of penicillin therapy were not adequate to effect a cure. During the last week of treatment pus continued to accumulate, and the cavity did not decrease in size.

CASE 10.—B. W., a white girl aged 2 years, was admitted on Jan. 3, 1944 with postpneumonic empyema, bronchopleural fistula and tension pneumothorax. Intercostal drainage was done the next day, releasing purulent fluid under pressure. Cultures showed type III pneumococci. Sulfamerazine therapy for the next fifteen days resulted in little or no improvement, and on January 18 penicillin was begun. Cultures yielded a coagulase positive Staphylococcus albus, which was sensitive to 0.156 unit of penicillin per cubic centimeter. Four thousand units of penicillin was injected intramuscularly every hour, and 40,000 units of calcium penicillin was instilled into the empyema cavity every twelve hours. The intercostal catheter was clamped off after each instillation of penicillin and was opened again one hour before the next injection. When there was no change in the patient's condition after six days of penicillin therapy a rib resection was done. Immediately the temperature fell to normal, and improvement was steady thereafter. Penicillin was discontinued three days after the operation.

In this case penicillin was of no value as far as could be determined. Failure to cure the lesion was to be expected in the presence of a bronchial fistula, but one would have expected some improvement in the child's general condition as a result of the therapy.

CASE 11.—J. C., a white man aged 67, was admitted on Dec. 15, 1944 with a putrid empyema known to be of at least three weeks' duration. On December 16 550 cc. of foul pus was removed. There was no growth aerobically, but a smear of the pus showed that it contained staphylococci, streptococci and diphtheroids. No anaerobic culture was made. On December 18 900 cc. of pus was removed and 100,000 units of penicillin was instilled. At this time the patient's temperature was 102 F. Aspiration of pus was repeated on December 19, 20, 21 and 23, 100,000 units being instilled on December 19 and 50,000 units thereafter. The pus lost its foul odor but did not decrease in amount, and the patient continued to have a temperature of 101-102 F. He developed abscesses in the chest wall at the sites of aspiration, so penicillin was discontinued and the empyema was drained.

It is possible that the patient might have responded to penicillin if treatment had been continued. However, his course during the first five days did not seem to indicate that this would occur, and in view of the infection in the chest wall it seemed safer to resort to surgical treatment.

CASE 12.—L. R., a colored woman aged 20, admitted on Jan. 20, 1944 suffering from disseminated lupus erythematosus, developed pneumonia of undetermined etiology in the left lower lobe on February 10. This improved somewhat with sulfamerazine therapy, but an effusion occurred and persisted. On March 2 1,500 cc. of green pus was aspirated from the left pleural cavity. Alpha hemolytic streptcocci, which were inhibited by 0.02 unit of penicillin per cubic centimeter, were recovered from the pus. On March 9 and for sixteen days thereafter the empyema was aspirated daily, and 50,000 units of penicillin was instilled after each aspiration. The pus became sterile after two days of therapy, and the amount of fluid that could be aspirated decreased rapidly. Small loculated collections of fluid formed that could be seen in the x-ray films for a month after treatment had been stopped, but these slowly disappeared. The patient died on June 30 from other causes. At autopsy the empyema cavity was found to be obliterated except for one very small collection of 8 to 10 cc of purulent appearing material. This was sterile on culture.

This case was successfully treated probably because of the extreme sensitivity of the infecting organism to penicillin. If the organism had been more resistant, it would have persisted in the loculation that formed and would have prevented a successful outcome.

CASE 13.—E. W.,[4] a white woman aged 26, was first admitted to the hospital in October 1943 with bilateral pulmonary tuberculosis and a large cavity on the right. Attempts to collapse the lung and obliterate the cavity were unsuccessful, so an intrapleural pneumolysis was done in two stages soon after the patient's admission. On December 13 x-rays for the first time showed fluid collected at the right base. On Jan. 19, 1944 the temperature suddenly rose to 104 F. and the patient experienced frequent chills. There was concurrent increase in the amount of fluid, and the patient became very ill. Aspiration and culture revealed no organisms, but anaerobic cultures were not done. The cavity in the lung was well collapsed, and the patient was responding well as far as the tuberculosis was concerned. Because of this good response and also because the disease was bilateral, her physician did not want to give up the pneumothorax. Consequently it was maintained, and the pleural cavity was aspirated frequently. The fluid became foul and increased in amount until 1,500 cc. was being aspirated every few days. At each aspiration the cavity was irrigated with saline solution and 50 cc. of hexylresorcinol was instilled.

On February 19 1,000 cc. of fluid was aspirated and 50,000 units of calcium penicillin was instilled. The fluid at this time was particularly foul, and cultures yielded an anaerobic streptococcus, unidentified anaerobic cocci and organisms resembling diphtheroids. Penicillin was injected twice daily for the next nine days, during which time the fluid became odorless and decreased in amount. From February 28 to March 6 the patient

4. This case is reported with the permission of Dr. W. A. Hudson.

received intravenously 100,000 units of sodium penicillin daily and then 50,000 units intravenously every day to March 13, when all medication was stopped. During this time the temperature came down and the patient gained weight and felt very well; the temperature remained normal with only occasional rises to 100 F. On March 21 the phrenic nerve was crushed. The temperature again rose on April 3 and the fluid became purulent. On April 14 225 cc. of thick greenish pus was aspirated, and after saline irrigation 50,000 units of sodium penicillin was instilled in 100 cc. of saline solution. This amount was repeated daily until April 24, then 50,000 units every two days to June 2, and then once weekly until June 26. During this time the amount of fluid aspirated varied between 150 and 200 cc. Cultures yielded anaerobic cocci and diphtheroids. The temperature at the time penicillin was started on April 14 was varying from 100 to 101 F. During the rest of April the temperature varied from normal to 100 F., with occasional rises to 101 F. and one to 103 F. Through May, however, the temperature was higher than 99 F. on only two occasions.

After penicillin was stopped, 100 to 150 cc. of fluid was aspirated occasionally through July 24. Cultures were sterile until this date, when an anaerobic nonhemolytic streptococcus was again found. The cultures are listed as follows:

Feb. 19, 1944, anaerobic diphtheroids; gram-positive rods.
February 21, anaerobic gram-positive rods.
February 25 and March 1, 4, 6, 8, 10 and 13, sterile.
March 27, anaerobic cocci.
April 11, anaerobic gram-positive rods.
April 15, anaerobic cocci; diphtheroids.
April 17 and 22, sterile.
April 24, anaerobic cocci.
May 1, anaerobic gram-positive cocci; anaerobic streptococci.
May 8, sterile.
May 15, anaerobic gram-positive rods and diphtheroids; aerobic alpha streptococci and diphtheroids.
May 22, sterile.
May 29, anaerobic cocci; Alcaligenes sp.
June 5, 6, 19 and 26 and July 3, sterile.
July 24, anaerobic nonhemolytic streptococci.

During the next six months the patient improved slowly. Penicillin in doses of 25,000 units to 50,000 units intrapleurally was necessary biweekly to prevent the reaccumulation of fluid. During this time it was finally decided to do an upper stage thoracoplasty; this was done in September 1944. The wound healed by first intention and at present, February 1945, the patient has only a small empyema cavity remaining and is about to be discharged to her home.

This case illustrates the value of penicillin in holding a putrid empyema in check, but it also illustrates the fact that an empyema is cured only when the cavity is obliterated. This may be accomplished by reexpansion of the lung or, as in this case, by moving the chest wall in to meet the lung. Any chemotherapy that is not accompanied by obliteration of the empyema is bound to fail.

Poisonous Spiders.—Tarantulas of the United States cannot be accepted as a menace. They are slow to attack a human being, are not numerous, and their poison lacks potency sufficient under normal circumstances to produce permanent or even serious harm. Mankind has reacted in some instances to poison secreted by certain species, as the giant Mygales of South America, but simple, local treatment is usually all that is necessary to offset the temporary effects. The bite of Atrax robustus of Australia, however, may cause serious symptoms and, under certain conditions, death to man. Fortunately this species is limited in its range; hence few instances of this kind are on record. The most universally distributed "dangerous" spiders are those of the genus Latrodectus, and it is they, more than all others, which are responsible for serious cases of spider bite.—Thorp, Raymond W., and Woodson, Weldon D.: Black Widow—America's Most Poisonous Spider, Chapel Hill, University of North Carolina Press, 1945.

OCULAR MALDEVELOPMENT IN EXTREMELY PREMATURE INFANTS

RETROLENTAL FIBROPLASIA: VI. GENERAL CONSIDERATION

T. L. TERRY, M.D.
BOSTON

In 1941 it was recognized that a massive growth of embryonic connective tissue occurring in the meshwork of a persistent tunica vasculosa lentis is linked with prematurity.[1] To my knowledge there are at least 162 cases at the present time. Dr. Stewart Clifford[2] has found that 12 per cent of the infants weighing 3 pounds (1,360 Gm.) or less at birth develop this disease. This percentage, based on less than 50 cases of prematurity, can be considered only a trend. If the true percentage of infants developing this disease is about 10, approximately 600[3] cases are to be expected in this country each year, which, if some prophylaxis is not found, will add materially to the 175,000 blind.

Typical well developed cases show seven characteristic findings:

1. There is opaque vascularized tissue behind the crystalline lens in which the vessels tend to radiate from a central point.
2. The eyes are abnormally small and as a result the eyelids, especially the lower, are sunken.
3. The anterior chambers are shallow, if not completely absent.
4. The irises retain their fetal-blue color, changing slowly to an abnormal gray-blue or dirty brown color.
5. Thin ciliary processes, appearing like teeth of a comb, can be seen in front of the opaque tissue when one looks through the dilated pupils from the extreme periphery.
6. The eyes have a searching nystagmus.
7. There is an apparent photophobia characterized by the infants covering the eyes when exposed to a brilliant light.

Frequently openings are seen in the opaque tissue through which one can observe the persistent hyaloid artery crossing the eye from the nervehead to the back of the lens. In some instances the opaque tissue seen at one side, through partially uninvolved vitreous, appears to have appreciable depth, extending posteriorly, often reaching the retina itself. Retinal separation may be and, at times, is the most obvious ocular disturbance.

Attempts to produce the disease in pouch young of the opossums and in newborn rats have failed, as have measures calculated to cause precocious closure of the hyaloid artery and tunica vasculosa lentis system. Although the pouch young of the opossum and newborn rats furnish immaturely developed eyes, it is possible

Read before the Section on Pediatrics at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

1. Terry, T. L.: Fibroblastic Overgrowth of Persistent Tunica Vasculosa Lentis in Premature Infants: Preliminary Report, Am. J. Ophth. 25:203 (Feb.) 1942; II. Report of Cases, Arch. Ophth. 29:36 (Jan.) 1943; III. Embryological Studies, Am. J. Ophth. 29:1409 (Dec.) 1942.
2. Clifford, Stewart: Personal communication to the author.
3. The number of cases is necessarily an estimated figure. Of the 125,671 premature births yearly in this country, as indicated from Vital Statistics (19:2 [Dec.] 1943), approximately 22,888 are extremely premature. If the true survival rate is represented by that of Hess and his associates at 43 per cent, then 11,131 should survive. If even 10 per cent of the survivors develop fibroplasia there should be over 1,000 cases per year. Because this statistical approach is founded on relatively meager numbers of reports of survival and of development of fibroplasia, subtracting 40 per cent for possible gross errors there would still be at least 600 per year.
4. Commonwealth of Massachusetts, Division of the Blind: Personal communication to the author.

that the failures to produce the disease can be attributed to eye characteristics different from those of the human being.

The hyaloid vascular system ceases to carry blood eight and a half months after conception,[5] and infants born earlier than this have a functioning hyaloid vascular system. In this meshwork the embryonic connective tissue can develop, thus producing retrolental fibroplasia. Because the disease process is not present at birth, developing from two to six months later, some factor resulting from premature birth must be responsible. It should be noted, however, that occasionally this condition, or one similar to it, usually unilateral, may be found at birth in the full term infant, having developed during intrauterine life. The ratio, since 1941, of fibroplasia in the premature and in the full term infants has been 162:4. Formerly, eyes involved with this disease were frequently considered to be eye cancers (retinoblastomas), thus warranting enucleation. The rarity of fibroplasia in the full term infant over the years is further shown by only 5 laboratory specimens in the collection of 12,000 enucleated eyes at the Massachusetts Eye and Ear Infirmary.

Many factors have been considered the probable cause of fibroplasia. These include heredity, intraocular inflammation, precocious exposure to light, precocious closure of the ductus arteriosus and the foramen ovale, an increase or decrease of oxygen in the blood, the lower temperature of the premature infants in the incubator in contrast to intrauterine fetal temperature, lack of adult maternal endocrine environment, precocious elevation of blood pressure, complications arising from the Rh factor differences in the mother and infant, inability to digest and assimilate food including vitamins, trauma or intraocular hemorrhage introducing the process, intraocular inflammation or infection, physiologic anemia of prematurity, changes in the blood such as premature establishment of the characteristic blood group and, finally, the causes of prematurity itself.[6]

Certain trends in biologic experiments indicate, but by no means prove, that the precocious exposure to light[7] may be the most important factor. The effects of light in exciting the disease process would more probably be related to the motor responses to light than to the stimulation of the retinal receptors. Animals whose eyes are extremely undeveloped at birth have their eyes sealed for a varying period after birth, and often light is further excluded by hair, usually dark, on the lids.[8] In the adult human being a pupillary response is obtainable in one opened eye when the light is carefully flashed so as to fall on the other closed eye, thus showing that sufficient light transilluminates the closed lid to produce a consensual pupillary reaction. Fibroplasia appears to occur more frequently in some places than in others. For example it is often found in one premature nursery, while other nurseries in the same city will have few if any cases. Similarly, 1 of twins, and in 1 instance 2 of triplets, have been known to develop the disease. The exposure to light varies with the frequency of examination and position in the nursery in relation to the location of the lights. Precocious light exposure as a possible cause can be determined most effectively if a fairly safe technic is worked out which will permit keeping the infants in the dark, or perhaps under a red light, and adequately covering the eyes while the infants are being examined or given nursing care under normal lighting conditions. Fibroplasia appears to be frequent enough to warrant bold measures, and it is my feeling that it is worth the risk to use a mydriatic or a miotic as a possible preventive measure. Which is better is open to conjecture, because the eyes in the dark have dilated pupils while in sleep the pupils are small. The status of the pupils in the fetus asleep and awake in the dark uterus can be different from the status of the pupils of the premature infant asleep and awake in the nursery, where it is in the light as much as or more than in the dark. That the pupil can react long before birth is indicated by the presence of small pupils and response to a mydriatic in premature infants weighing less than 2 pounds (907 Gm.). Ida Mann[9] states that the sphincter pupillae morphologically appears capable of activity in the four months fetus. The use of a mydriatic, preferably atropine because its effect is more permanent, would be the easier. In the use of both drugs, however, there is danger of favoring the development of complications, such as glaucoma with atropine or posterior synechia with pilocarpine. If, in using atropine in one eye only, no difference in the frequency of development of fibroplasia is observed in the two eyes of 50 or more premature infants so handled, this drug could be discarded as a preventive measure. The same procedure could be tried with miotic drugs, but one should remember that their effect is temporary, lasting perhaps not over two hours at best.

Treatment through direct surgical attack, through use of radiation or through an attempt to seal the hyaloid artery with diathermy has ended disastrously. If no treatment is given, in some instances there is a spontaneous reduction in amount of opaque tissue, but the eyes usually fail to grow normally. At times cataract and corneal opacities develop in addition to glaucoma and posterior synechia, which have been previously mentioned. Despite the ability in all extremely premature infants to see these fetal vessels of the hyaloid artery and tunica vasculosa lentis, which should normally disappear, it has not been possible as yet to determine which of the premature infants will develop the disease. As the fibroplasia develops after the infant has completed its incubator life and has been discharged to its home, many stages of the development have not been observed.

To prevent the development of glaucoma after the disease has arisen, a miotic, usually 1 per cent pilocarpine, is used daily. As there is a tendency for posterior synechia to develop, a combination of powerful synergistic mydriatics[10] which keeps the pupil dilated only a few hours is used once weekly. One drop of this medicine suffices. The parents are advised to observe the eyes after mydriasis to see if the pupil fails to dilate or to note any tendency of the pupil to be unround, an evidence of synechia formation. These preventive measures appear to lessen the frequency of two dangerous complications.

several severely involved eyes, with probable beneficial effects in about half.

In giving guidance and advice to the parents, the following points are brought out: First, they must adjust themselves to the probability that their baby will not see; that blind people are happy people and can become normal, healthy, useful citizens. Second, the child should be given normal affection but should not be pampered, being treated as though normal. Third, toys that are interesting from the standopint of shape and sound should be provided. Fourth, companionship with other children of the same age should be sought. This can be obtained at blind baby nurseries. Fifth, music, which has been found almost invariably to be enjoyed and appreciated, should be given to these children, in some instances with music lessons. Sixth, school, on advice from the Perkins Institution for the Blind, is to be delayed until the seventh year.

As there is no suspicion that this is a hereditary disease, the parents are told that they should not be hesitant about having more children.

SUMMARY

Over 10 per cent of the infants born very prematurely, weighing 3 pounds or less at birth, can be expected to be blind from retrolental fibroplasia. If this percentage remains, at least 600 cases will occur annually, thus increasing the blind census materially.

The typical characteristics of the disease are opaque vascularized membrane behind the lens, microphthalmia, shallow anterior chambers, fetal-blue color of the iris, thin ciliary processes in front of the opaque tissue, searching nystagmus, apparent photophobia, persistent hyaloid artery and often retinal separation.

The basis of the disease lies in the presence of a functioning hyaloid artery and tunica vasculosa lentis system in all infants born even three or four weeks prematurely.

Of all the probable causes listed, precocious exposure to light is considered the most tenable, and preventive measures should be taken.

For prevention, mydriatics and miotics could be used but if considered too drastic the infants should be kept in a dark room with a red light and the eyes covered adequately during examinations and nursing care.

Treatment consists in preventing the most common complications glaucoma and posterior synechia by use of miotics and mydriatics. Surgical and radiation therapy have proved unsuccessful. A surgical attempt, however, to establish a new vascularization of the ciliary body with the episclera is being done with some beneficial results.

ABSTRACT OF DISCUSSION

DR. HEYWORTH N. SANFORD, Chicago: No doubt those who have worked many years with the premature infant have been wondering why they never observed this eye dyscrasia. I observed 1 instance of retrolental fibroplasia in a premature infant weighing 2 pounds (907 Gm.) about two years ago. Since then Dr. Justin Donegan has also examined the eyes of all our premature infants, but we have failed to observe any more. This is not surprising and I would emphasize that Dr. Stewart Clifford observed that they occur in only 10 per cent of premature infants weighing 3 pounds (1,360 Gm.) or less. While the average obstetric service will run about 10 per cent of premature infants, the majority of these infants will be over 3 pounds in weight, as were those that we studied. As only about half a dozen of these were under 3 pounds, this would agree with Clifford's estimate of 1 in 10 premature infants of 3 pounds or less. When Dr. Ethel Dunham made her survey on the premature mortality in hospitals throughout the United States in 1930 she found that the average premature mortality was about 26 per cent. In Chicago from 1931 to 1937 Dr. Edith Potter reported that the premature mortality for Lying-In Hospital was 20.7 per cent. Since 1938 there has been a drive in Chicago as in many other cities to lower the premature mortality. Certainly the premature mortality now in those hospitals in Chicago which offer adequate premature care is well below 20 per cent. This means a reduction in ten years of approximately 8 per cent, and most of this decreased mortality has been in premature infants under 3 pounds. Premature infants that once were born in hospitals with no facilities for premature care or in the home and would thus die shortly are now removed to hospitals with facilities for premature care and are saved. I wonder if we are not having more of these very small premature infants to study, which prior to this time we did not have an opportunity of seeing under the conditions that we have today. While this is undoubtedly a new disease, it is one that has not before been apparent because the type of child carrying such a deformity has not herctofore been saved in sufficient numbers to demonstrate this condition. By increasing the span of life of the average adult through the last decades we have increased the incidence of some diseases. Here by saving the lives of very small premature infants that heretolore have perished we have likewise added another condition that we must now endeavor to find a therapeutic means of combating.

DR. E. V. L. BROWN, Chicago: Incubator care has saved many lives, but as a result of it, apparently, there are several hundred blind babies in the country. Previous to 1935 some sixteen eyes had been removed by me for glioma retinae—neuroblastoma—and all were gliomas. But in the next five years I was responsible for the removal of six more, four of which proved to be retrolental fibroplasia and not glioma and need not have been removed at all. Dr. Terry postulates that this condition may be due to faulty development of the ciliary body basically. The mother is almost always the one who discovers this condition. She usually, it seems, finds it while she is bathing the child and the light happens to strike the pupil just right and she sees the mass behind the pupil. Ordinary observation by other members of the family or by the family doctor or pediatrician may not corroborate what she has seen. We should give every mother who has a premature child, at least before the seventh month or of only 3 or 3½ pounds (1,360 to 1,587 Gm.) of weight instructions to watch carefully the child's eyes throughout the first year. I do not know of cases that have occurred later than the first year in which there is any evidence that the condition was not present before that. It is occurring in our large centers of population certainly in a considerable number of cases. The number that Dr. Terry has seen, around 100 in the neighborhood of Boston, seems to be huge, but the late Dr. S. R. Gifford had seen 15 or 20 cases. Dr. Gradle told me that he had seen some 15 cases. My colleague Dr. J. M. Donigan and I have seen between 15 and 20 cases. Dr. Richard Gamble has seen some 5 cases. So we are up to around 75 or 80 just among five or six of us here in Chicago, in the last couple of years.

DR. A. J. STRICH, Chicago: I should like to report briefly on a negative series of experiments on the etiology of fibroplasia conducted at the Children's Memorial Hospital in Chicago by Dr. Gamble and myself. We have seen in the past few years 16 cases of fibroplasia, and Dr. Terry has been in consultation on 2 of them. Working on the presumption that this disease, which used to be rare, suddenly became quite frequent in the last few years and on the presumption that these children are not born with fibroplasia but show it after a few months of their lives, we have surveyed several Chicago nurseries from which our 16 patients came, looking for the factor which made the disease common. We thought of sulfonamides, but only a few of our patients had had them. We thought of vitamin K, but only 1 or 2 of them had had it. But with only 1 exception all of these babies came from nurseries where the so-called germicidal lamp was employed. This is an ultraviolet ray producing lamp and it has been used for the past few years to

sterilize the air in nurseries. We decided to investigate this point experimentally. We received 12 female pregnant rats and used ten families as an experimental group which was exposed to the germicidal lamp. We set two families aside in a dark room. The germicidal lamp is a powerful lamp. Some of the families which received more irradiation were burned to death. The ones that received a little less irradiation survived but developed cataracts. Rats seemed to be animals which would be suitable for that experiment because rats are being born with a hyaloid system still present and they have blood vessels around the lens and these blood vessels disappear in from two or three weeks. The blood vessels continued to disappear in two or three weeks in our working group just as fast as in our control group, which might prove the point that either the germicidal lamp is not the cause of fibroplasia or that rats do not develop fibroplasia. However, we shall not give up and we intend to find out how many of the children throughout the country having fibroplasia were kept in nurseries where they were exposed to continuous light, be it germicidal or not.

DR. T. L. TERRY, Boston: Some of the points brought up are answered in previous publications, and others can be based on poorly supported conjecture.

INFLUENCE OF NEOSTIGMINE METHYLSULFATE ON PREECLAMPTIC PATIENTS

AND CHOLINESTERASE ACTIVITY OF PLACENTAS FROM NORMAL AND PREECLAMPTIC PATIENTS

ROBERT A. WOODBURY, M.D., PH.D.

LIEUTENANT PAUL H. FRIED
UNITED STATES ARMY AIR FORCES

A number of reports [1] state that the normal pregnant woman has some substance in her blood which will neutralize posterior pituitary injection and that an injection of this substance into preeclamptic patients will occasionally initiate the onset of convulsions. The investigations of Schockaert and Lambillon [2] and of Dieckmann and Michel [3] demonstrated that approximately 65 per cent of preeclamptic and eclamptic patients show abnormally great and prolonged blood pressure elevations and antidiuretic responses to pitressin. Since the studies of Necheles and Neuwelt [4] indicate some antagonism between acetylcholine and pitressin, the question arose whether acetylcholine activity is altered or abnormal in eclamptic toxemia.

There are some data which suggest that a relative decreased acetylcholine activity may occur in preeclampsia. Human placentas contain large amounts of acetylcholine, as was shown by Chang and Gaddum,[5] who reported 28 micrograms per gram of fresh placenta. Hofbauer [6] reported acetylcholine values for five whole placentas of eclamptic patients and though no placental weights were given he concluded that these values were significantly lower than the normal values of Chang and Gaddum. Hofbauer [6] also quoted investigations at Harvard University to show that the cholinesterase activity of preeclamptic placentas was higher than normal. However, personal communication from the Harvard laboratory [7] indicated that the work which was quoted was incomplete and was not ready for publication. Therefore cholinesterase activity was determined in placentas from normal and preeclamptic patients.

The naturally occurring acetylcholine can be potentiated by inhibiting cholinesterase, the enzyme which destroys it. Neostigmine methylsulfate has this action. It seemed worth while to investigate the effects of this drug on preeclamptic patients, since preparations of veratrum viride, another parasympathomimetic drug, are useful in treatment of preeclampsia.

METHODS AND MATERIAL

Eight patients, pregnant seven to nine months, have been studied. Five were diagnosed preeclamptic and showed edema, proteinuria, visual disturbances and hypertension of recent origin. Two were hypertensive without evidence of any toxemias of pregnancy and 1 was a normal control.

The blood pressure studies were accomplished with the hypodermic manometer.[8] Neostigmine methylsulfate was administered until definite effects occurred. One to three intramuscular injections of 0.25 mg. at intervals of ninety minutes were followed at hourly intervals by one or two intravenous injections of 0.02 to 0.25 mg. The drug was discontinued whenever uterine activity started or whenever either the systolic or the diastolic pressure was elevated an additional 20 mm. of mercury. This method of administration was selected with four important facts in mind: (1) The susceptibility to the drug might vary greatly, (2) as with physostigmine [9] there might be an appreciable latent period even after intravenous injections, (3) the interference with the destruction of acetylcholine might allow liberation of sufficient amounts from the placenta to cause excessive and dangerous uterine activity and (4) preeclamptic patients might be abnormally susceptible to the stimulative action of the drug at prepostganglionic synapses of the sympathetic nervous system (nicotinic action).

Cholinesterase activity was determined in placentas of 8 normal and 13 preeclamptic patients by Torda's modification [10] of Glick's method.

RESULTS AND COMMENT

Individual susceptibility to neostigmine appeared to vary greatly. Pronounced effects were produced in 1 case with 0.25 mg. intramuscularly and 0.023 mg. intravenously, while in another case 1.00 mg. intramuscularly and 0.75 mg. intravenously was necessary to produce definite effects.

In the preeclamptic and the control patients uterine activity and vascular effects appeared rather suddenly

after a definite latent period of ninety to one hundred and twenty minutes even after intravenous injections. In 1 normal patient and in 1 hypertensive patient neostigmine failed to lower the blood pressure though uterine activity was initiated. In the second hypertensive patient neostigmine elevated the arterial pressure. These observations indicate that small to moderate amounts of neostigmine do not lower the arterial pressure in control noneclamptic gravid patients even though hypertension may be present. They suggest that the drug may initiate labor during the seventh and eighth months, which differs from the reported absence of effect on the uterus when used as a pregnancy test early in pregnancy.[11]

In 3 of the 5 gravid preeclamptic patients neostigmine, after initially elevating the blood pressure 10 to 20 mm. of mercury, produced chill, a temperature elevation of 1 to 2 degrees F. and a reduction of the arterial pressure from 185/105 to 143/83, from 220/125 to 124/92 and from 145/82 to 100/60 (see plot of the arterial pressure of 1 case in figure 2). The arterial pressure remained low for four to eight hours until the action of the drug had diminished and until the excitement, activity and pain associated with labor had increased the blood pressure. In the other 2 preeclamptic gravid patients neostigmine not only failed to lower the blood pressure but in 1 of these it raised the pressure 20 mm. of mercury. These elevations could result from the stimulating action of acetylcholine on autonomic ganglions and of course are not beneficial to the patient. The fact that neostigmine sometimes lowers and sometimes increases the arterial pressure may be taken as indicating that there are several different types of preeclampsia; sometimes one altered physiologic process is important, while in other patients different processes may be altered to a larger extent.

One of the preeclamptic patients who showed a pronounced reduction in blood pressure from neostigmine was again tested ten hours post partum. At this time neostigmine failed to lower the arterial pressure (fig. 2). Adequate dosage had been administered, since 0.32 mg. of acetylcholine administered intravenously over a period of twenty seconds lowered the arterial pressure 40 mm. of mercury, while in the absence of neostigmine only minimal effects are produced by doses twenty to sixty times as large.[12] These data are interpreted to show that pronounced effects can be obtained from moderate amounts of neostigmine when administered ante partum. This is apparently due to the fact that a large depot of acetylcholine is present in the placenta. The neostigmine inhibited its destruction and allowed greater acetylcholine activity.

Preeclamptic placentas had a significantly greater cholinesterase activity than those of normal women. Values expressed as micrograms of acetylcholine chloride hydrolyzed per milligram of dried placenta per second were for normal women 6.0 ± S. E. of 0.15 and for preeclamptic patients 9.4 ± S. E. of 0.19. Statistical evaluation showed that $t = 4.0$, which indicates that the probability of this difference occurring by chance is 1 : 12,000. The presence of the high cholinesterase activity in the placenta may be a protective mechanism or may be a contributing factor to the condition of preeclampsia.

As shown in figure 1, neostigmine increased the standing waves in the radial pressure pulses. This change of the pulse contour indicates that peripheral vasoconstriction occurred in the vessels of that arm.[13] Apparently muscular and cutaneous vessels were constricted. Intensive widespread cutaneous vasoconstriction could account for the chill but cannot account for the pronounced reduction in arterial pressure in these patients.

This generalized vasoconstriction should increase arterial pressure and retard blood outflow from the arterial tree. Since the blood pressure is reduced and since the rate of descent of pressure during the last part of systole is increased (figure 1) the outflow of blood from the arterial tree must actually be rapid. This rapid flow can be and probably was into the uterus and placenta.

Provided this flow is augmented, any sudden interference with it would be expected to cause a definite increase in maternal arterial pressure. Each uterine contraction constitutes an interference with maternal uterine placental blood flow, since these hinder maternal blood flow into the uterine placental area and squeeze maternal blood from the uterine sinusoids.[14] The fact that in these patients at this time uterine contractions elevate the maternal arterial pressure 40 to 50 mm. of mercury during systole and 20 mm. of mercury during diastole provides proof that maternal uterine placental blood flow and volume are large. Control postpartum neostigmine administrations did not significantly alter the arterial pressures in these patients.

These data can be interpreted as evidence that neostigmine administered to preeclamptic gravid patients decreases the blood flow to muscle and cutaneous areas and in some patients increases blood flow to the uterus

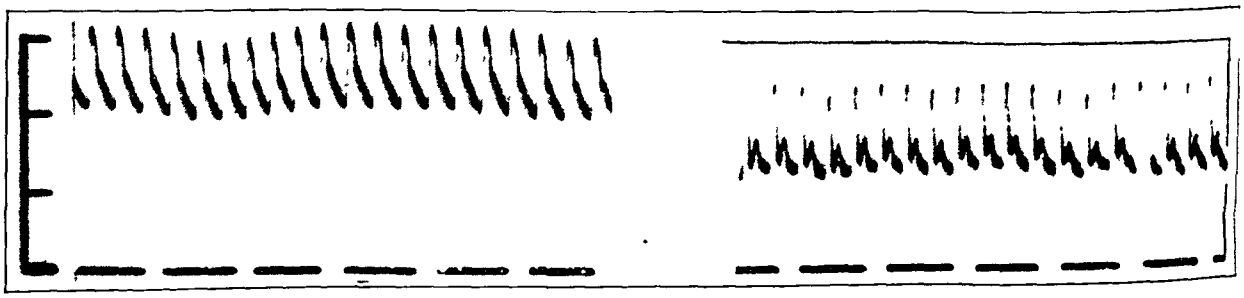

Fig. 1.—Radial pressure pulses from preeclamptic patient. Blood pressure scale is shown in units of 50 mm. of mercury. Base line is interrupted at intervals of two minutes. Tracing at left was recorded at 12 o'clock noon. Neostigmine methylsulfate was injected intramuscularly 0.25 mg. at 12: 15 p. m. and intravenously 0.023 mg. at 1: 15 p. m. Chill and uterine activity were present at 2: 10 p. m. Tracing at right recorded at 2: 30 p. m.

and placenta. This increased uterine blood flow in the presence of a lowered arterial pressure can occur only when resistance within the uterine circulation is decreased. Prior to neostigmine administrations the maternal placental resistance was evidently high and maternal placental blood flow may have been adequately maintained only because the blood pressure was elevated. The fact that acetylcholine [15] and neostigmine [11] produce uterine hyperemia constitutes evidence to support the contention that neostigmine reduces the resistance within the uterine vascular bed. The cutaneous effects differ from those observed in normal and vasospastic patients in whom neostigmine increased the skin temperature and dilated small arteries but did not produce flushing.[16]

Neostigmine appeared to induce labor in these 8 patients who were pregnant seven, seven and one-half, eight, eight and one-quarter, eight and three-quarters, nine, nine and nine months. Uterine activity was normal and delivery was uncomplicated in 6 of the 8 patients, although 1 infant, seven months premature, died four hours post partum. In the other 2, who were multiparous eclamptic patients and who each received 1 mg. intramuscularly and 0.75 mg. intravenously, the uterus became hyperactive and cervical effacement and dilatation were delayed. Labor was dangerously prolonged to thirty-six and forty-eight hours. One of these

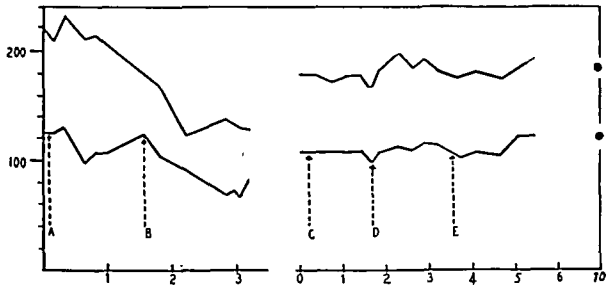

Fig. 2.—Plot of systolic and diastolic blood pressure of a preeclamptic patient who received neostigmine methylsulfate. Time indicated in intervals of one hour. At left, ante partum: At two hour intervals three intramuscular injections of 0.25 mg. of neostigmine methylsulfate were administered prior to *A*. The arterial pressure was increased 30 mm. of mercury during systole and 20 mm. of mercury during diastole. Two hours after the last intramuscular injection, an intravenous injection of 0.25 mg. of neostigmine methylsulfate was administered at *A*. Chill occurred and uterine contractions were initiated at *B*. The reduction of arterial pressure continued for four hours and then slowly rose as labor progressed. The baby was delivered nine hours after point *B*. At right, post partum: Seven hours after delivery at *C*, 0.5 mg. of neostigmine methylsulfate was administered intramuscularly. At *D* 0.25 mg. was administered intramuscularly. At *E* 0.25 mg. was administered intravenously. The arterial pressure was determined every half hour. No significant reduction was observed.

infants, seven and one-half months premature, died seventeen hours post partum. The death of these 2 infants can probably be ascribed to prematurity and the presence of toxemia. Neostigmine administrations probably were not a contributing factor. Used with caution and with proper allowance for its latent period, it may be less dangerous in some patients and no more dangerous in others than present medical methods of inducing labor. If used without discretion it would be expected to produce more detrimental effects than those observed with careless use of other methods.

The influence of neostigmine on convulsions of eclamptic patients has not been determined.

The observation that some preeclamptic gravid patients respond differently to neostigmine than normal gravid patients suggests that in preeclampsia (*a*) the tissues respond abnormally qualitatively or quantitatively to acetylcholine or, less likely, (*b*) the placenta and other tissues produce a slightly different choline derivative than is normally present.

SUMMARY AND CONCLUSIONS

Individual susceptibility to neostigmine seemed to vary greatly, and even when administered intravenously a latent period of ninety to one hundred and twenty minutes was present. In all of the gravid patients it seemed to induce labor. In 2 of the patients in whom administrations were continued for twelve hours or longer the uterus became hyperreactive and hypertonic, resulting in a prolonged labor.

The presence of preeclampsia influences the type of response to moderate amounts of neostigmine. The drug does not lower the blood pressure of gravid patients unless they are preeclamptic. It does lower the arterial pressure of some but not all preeclamptic patients. The reduction in arterial pressure was always preceded or accompanied by chill, slight temperature elevation and initiation of labor. Preeclamptic patients have high resistance in the maternal placental vascular bed, and the reduction of blood pressure seems to be caused by decreased peripheral resistance in the uterine vascular bed. It seems to be accompanied by vasoconstriction of muscular, cutaneous and possibly renal vessels.

The observation that different preeclamptic patients may respond differently to moderate doses of neostigmine contributes additional support to the belief that there may be several different types of preeclampsia.

The cholinesterase activity of placentas from preeclamptic patients is greater than from normal patients.

ABSTRACT OF DISCUSSION

DR. A. R. ABARBANEL, Washington, D. C.: The work of Dr. Woodbury and his associates has apparently opened up a relatively new field in the possible treatment of toxemias of pregnancy. But, as they emphasize, neostigmine can be a double edged sword. They did mention that, but in 1 case the blood pressure did rise. That, of course, will depend on whether or not its action on the ganglion predominates over the peripheral action. The point that interested me in particular was the finding of a high cholinesterase in the toxemic placenta as compared to the normal. Cholinesterase is present in such superabundance in the tissues that it is hard to explain why there should be an actual increased amount in the placenta, except possibly that the placenta was putting out more acetylcholine in order to offset the toxic substance which was producing the unit of pathologic functioning, which most obstetricians now believe to be angiospasm. Whether this substance comes from the posterior pituitary, as many men, notably Dr. Hofbauer, believe is difficult to prove. There may be another factor in the increased cholinesterase, and that is the question of ions. We know that the cell is influenced by its ionic content and its ionic environment. It is quite possible that either a high calcium or a high potassium might have been a contributory factor. Early in pregnancy the uterus is relatively high in magnesium and low in calcium, but as term approaches the ratio of calcium and magnesium changes so that calcium becomes high, accounting for its increased irritability, and magnesium becomes low. Hyperirritability and hypertonicity of the uterus lead to many complications. One of the most severe of these is tetany of the uterus, in which we may get fetal anoxemia and eventual death or even actual rupture of the uterus. It is possible that in these 2 cases in which hyperirritability or hypertonicity was encountered atropine might have been effectual. There is another drug which is extremely effectual and which will abolish tetany of the uterus practically within thirty to sixty seconds. This drug is magnesium ion. Administered either as the sulfate or the gluconate intravenously, it prolongs the conduction rate

in the uterus so that it gives the uterus more of a restorative or recuperative phase following a muscular contraction. Magnesium will work against every type of oxytocic I have tried, including posterior pituitary injection, pitocin, pitressin, ergonovine, quinine and also when Bandl's ring contracture was encountered.

DR. R. A. WOODBURY, Augusta, Ga.: The suggestion made by Dr. Abarbanel that magnesium might be included with the treatment of neostigmine is excellent. We did not give these patients magnesium with neostigmine because it would have confused the story as to the action of the neostigmine, and yet it may well be that the administration of magnesium or some of the parasympatholytic drugs along with the neostigmine may remove the danger of the use of neostigmine in preeclamptic patients. It may protect the fetus from the hyperirritable uterus that neostigmine can produce.

Clinical Notes, Suggestions and New Instruments

COMPLETE URETERAL DUPLICATION TERMINATING IN THE SAME URETEROCELE AND RESULTING IN SEVERE HYDRONEPHROSIS

VIRGIL S. COUNSELLER, M.D.
AND
DAVID S. CRISTOL, M.D.
First Assistant in Urology, Mayo Clinic
ROCHESTER, MINN.

Of all the congenital abnormalities of the urinary tract, ureteroceles are among the most amenable to successful surgical treatment.

As reported by Thompson and Greene,[1] the majority of ureteroceles are congenital in origin, occur twice as frequently among women as they do among men, are most reliably diagnosed by cystoscopy and are best treated transurethrally by simple fulguration of the small ureteral orifice or a combination of ureteromeatotomy and fulguration of the walls of the ureterocele. These authors recognized that the presence of destroyed renal function or urinary calculi which could not be removed transurethrally necessitated open operation. While in the case that we are reporting there were features characteristic of moderate obstruction of the vesical neck, such as pronounced dysuria, a large atonic bladder, urographic evidence of a left nonfunctioning kidney and pyeloureterectasis of the other kidney and ureter, there have been numerous cases in which the ureterocele prolapsed through the urethra to cause intermittent complete urinary retention. Such a case was recently reported by Emmett and Logan.[2]

The case reported here presents several interesting features. First, it demonstrates how rapidly an obstructive lesion caused by a congenital ureterocele can result in severe hydronephrosis. Second, it is unique in that there was complete ureteral duplication with the two ureters opening into the same ureterocele. Finally, in this case a rather extensive surgical procedure was necessitated which was attended by a successful result.

REPORT OF CASE

A white girl aged 3½ years was brought to the Mayo Clinic in August 1944. A letter from the referring physician stated that the child, who had been the product of a full term normal spontaneous delivery and weighed 8½ pounds (3.8 Kg.) at birth, had first been taken ill with fever, urinary frequency, dysuria and pyuria at 11 months of age. A course of sulfanilamide therapy caused successful arrest of symptoms, though pyuria persisted. In the two years preceding this admission the child had suffered from several similar attacks, all responding symptomatically to sulfanilamide except for persistent pyuria, which frequently was grossly noticeable. Three days before admission to the clinic the patient had a severe attack with elevated temperature and dysuria, which was so intense that it caused the patient to avoid micturition even though the bladder was apparently overdistended.

A review of systems made by questioning the patient's mother gave negative results. The patient was the only child of two healthy parents. The past medical history was negative except for an attack of infantile eczema, which had been absent for the past year. The child's developmental history was entirely normal.

Physical examination revealed that the child was well developed but obviously acutely ill. The patient's oral temperature was 102.8 F. The pulse rate was 120 per minute. The respiratory rate was 28 per minute. The results of laboratory analyses were as follows: Erythrocytes in the urine were graded 1 and leukocytes were graded 3 (on the basis of 1 to 4, in which 1 represents the smallest and 4 the largest number of formed elements). Staphylococcus aureus and Streptococcus fecalis were cultured from the urine. The concentration of urea was 26 mg. and that of hemoglobin was 10.6 Gm. per hundred cubic centimeters of blood. Erythrocytes numbered 3,620,000 and leukocytes numbered 9,600 in each cubic millimeter of blood. A flocculation test for syphilis gave negative results. The first strength of the tuberculin test was negative. A roentgenogram of the thorax appeared normal. An excretory urogram was largely obscured by gas but did show moderate right pyeloureterectasis and a vesical outline which was larger than normal. Accurate evaluation of the left kidney and ureter was impossible because of greatly reduced function, with only questionable visualization of the upper calix.

Double ureter and hydronephrotic kidney with only thin shell of atrophic renal cortex remaining. Both ureters are much dilated and terminate within the same small segment of ureterocele.

On cystoscopy performed with the patient under ether and nitrous oxide anesthesia, a large volume of urine was found in the bladder, which was greatly distended and slightly trabeculated. Neither ureteral orifice could be seen. In the region of the left ureteral orifice was a large soft structure which the cystoscopist believed probably represented a ureterocele and which he thought might be producing obstruction at the vesical neck. Because the exact nature of abnormality within the bladder could not be accurately determined cystoscopically and because the function of the left kidney seemed to have been destroyed, suprapubic exploration was advised.

With the patient under ether and nitrous oxide anesthesia, and through a primary low midline incision, the bladder was opened. It appeared greatly enlarged and was the seat of a moderate amount of inflammation. The left side of the bladder was occupied by a large ureterocele and it was found to contain two ureteral orifices. The right ureteral orifice appeared to be normal. On transvesical excision of the ureterocele it was apparent that one orifice led into a much dilated ureter while the other orifice led into a large pocket, which on further exploration proved to be a hydroureter. The original incision

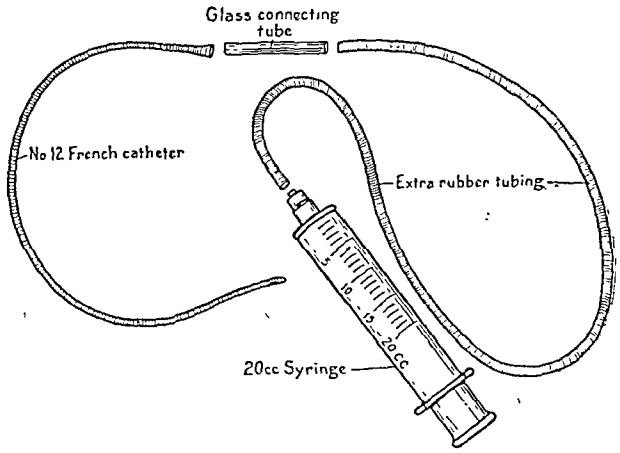
was extended transperitoneally and both of these dilated ureters were found to join a hydronephrotic left kidney in which more than 90 per cent of the renal substance had been destroyed. Both dilated ureters as well as the hydronephrotic left kidney were removed transperitoneally. The right kidney was found to be normal and had a normal ureterovesical opening. One small 18 F. bivalved catheter was inserted into the bladder as a cystostomy tube and a 4 F. ureteral catheter was left in the right ureter with its upper end in the renal pelvis and its lower end extending through the urethra. The peritoneum was closed after 5 Gm. of sulfanilamide had been left in the peritoneal cavity; 2.5 Gm. of sulfanilamide was left in the incision, which was closed with double continuous number 1 chromic catgut with single interrupted chromic sutures in the fascia. A split rubber tube was left in the incision. The patient was given a transfusion of 250 cc. of compatible blood at the completion of the operation.

The removed specimen consisted of a kidney, double ureter and a portion of the bladder. The kidney was considerably hydronephrotic, with almost complete destruction of the renal substance. One ureter, believed to be the functional one, was dilated throughout with a diameter slightly more than 1 cm. Parallel to the ureter was another one measuring approximately 25 cm. in length and approximately 4 cm. in diameter.

The split rubber tube was removed on the second day after operation. The ureteral catheter was withdrawn from the right ureter on the fourth postoperative day. The cystostomy tube was removed on the fifteenth day and thereafter the suprapubic fistula remained dry and healed rapidly. The patient was dismissed from the hospital on the twenty-third postoperative day. At this time the dysuria was reduced by more than 50 per cent but Streptococcus fecalis was cultured from the urine. The patient was dismissed with instructions to receive alternate courses of sulfathiazole and a mandelic acid preparation. She was taken home to the care of her home physician, who sent her back to us one month later for a routine follow-up visit. Examination at the time disclosed that the patient appeared and felt perfectly well. Streptococcus fecalis was again cultured from the urine, which now appeared to be crystal clear. A further course of mandelic acid therapy was prescribed for the patient.

The patient was reexamined in January 1945. Her parents volunteered the information that she was enjoying perfect health and was voiding normally. No residual urine was present in the bladder. An excretory urogram revealed that the right kidney was functioning well with minimal pyelocaliectasis. The vesical outline appeared normal. Because Streptococcus fecalis was still present in the urine, mandelic acid therapy was continued.



RECTAL INSTILLATION OF AMINOPHYLLINE IN INTRACTABLE ASTHMA

ALVAN L. BARACH, M.D., NEW YORK

Intravenous injection of aminophylline in patients with intractable asthma has become recognized as an exceedingly valuable therapeutic remedy following its introduction in 1937.[1] Since termination of bronchial spasm has been satisfactorily accomplished in more than 200 patients by rectal instillation of this drug, it has been repeatedly employed by nurses and by patients themselves in a program of bronchial relaxation.[2] The relief of bronchial spasm takes place in ten to thirty minutes, more gradually than with intravenous injection, but the side effects on the circulation, such as dizziness and faintness, are rarely encountered and have in no instance been troublesome. Nausea and vomiting may take place after large doses, as in intravenous injection, but are much less apt to occur if the patient is in the reclining position for one hour after its administration. The intravenous ampule of 20 cc. containing 0.48 Gm. of the drug has been employed, but it is much less expensive to use powders of 0.5, 0.6 or 0.7 Gm., dissolved at the time of administration in 20 cc. of tap water. There is admittedly less uniformity in absorption from the rectum than from the intravenous injection, but the availability of the method to the patient outweighs this relatively minor disadvantage.

The apparatus consists of a 20 cc. glass syringe, a No. 12 French rubber catheter and a connecting rubber tube attached to the open end of the catheter, approximately 18 inches in length and ⅛ inch in diameter.

At the time of treatment a powder of 0.6 Gm. is dissolved in 20 cc. of tap water and drawn into the glass syringe. The syringe is placed on the bedside table prior to introduction of the rubber catheter. Lubrication of both the anal mucosa and the rubber catheter is important to prevent irritation from long continued use. The catheter is then easily inserted into

Apparatus for rectal instillation of aminophylline.

the rectum for a distance of 2 or 3 inches; the rubber tube connection is brought forward in front of the patient, the syringe attached and the aminophylline delivered into the rectum. The catheter is then pinched tightly, to prevent drops of the solution from wetting the bed, and withdrawn. Other advantages of the method are that (1) the anal canal is not dilated by a large enema tube, (2) there is a minimal introduction of air, which may take place with the use of a tube and funnel, and (3) there is no irritation whatever if properly employed.

Although aminophylline is by far the most valuable drug in restoring sensitiveness to epinephrine, it must be borne in mind that patients will at times become refractory to aminophylline also. The treatment of this unfortunate complication is beyond the scope of the present paper, but it may be pointed out that the drug must then be discontinued and recourse had to other methods of bronchial relaxation, such as helium-oxygen therapy or colonic ether, in order to restore the patient's responsiveness to aminophylline.

SUMMARY

Rectal instillation of aminophylline by means of a No. 12 French catheter, a rubber tube connection and a 20 cc. glass syringe has certain advantages over intravenous injection in the treatment of intractable asthma. The procedure has been carried out by nurses, relatives and patients themselves without delay or difficulty. Circulatory side-effects of rapid intravenous injection, such as dizziness and faintness, were rarely encountered and never troublesome.

Council on Foods and Nutrition

SPECIAL ARTICLE

This is the eighth of a series of articles discussing the significance of protein nutrition in health and disease. This material was prepared by the authors at the request of the Council and has been authorized for publication.

GEORGE K ANDERSON, M D, *Secretary.*

SELECTION OF PROTEIN CONTAINING FOODS TO MEET PROTEIN REQUIREMENTS

DOROTHEA F. TURNER, S.M.
CHICAGO

In planning a dietary regimen appropriate in protein content for different health and socioeconomic conditions, several factors must be considered. Some evaluation must be made of the nutritive efficiency of proteins in a mixed dietary; selections must be made of the proper kind and amount of protein containing foods which may be used for various dietary prescriptions; and, finally, adaptations will have to be made to correspond with the patient's food habits, income and rationing allowances.

Space has not been given to itemizing numerous meal plans, but rather a procedure has been outlined whereby it will be possible to make up a dietary appropriate for each individual patient by making simple adaptations of a basic pattern of food intake.

THE NUTRITIVE EFFICIENCY OF PROTEINS IN A MIXED DIETARY

Is a quantitative appraisal of the amino acid content of the mixed dietary now in order? If so, this would be the most direct way to assess the nutritive efficiency of the food intake. While an approach has been made to an approximation of the amino acid requirements and to the selection of the appropriate quantities and combinations of food proteins which will meet these needs, the dietitian is not as yet adequately prepared to calculate accurately the amino acid content of the diet. As Block and Bolling [1] have stated, "It should be recognized that the methods used for estimating amino acids are not of equal precision. Errors are introduced by the formation of inhibiting substances or the partial destruction or modification of certain amino acids during hydrolysis. Mechanical and solubility losses also play a part." Nevertheless, present methods are of special use in comparative investigations and, if employed in conjunction with biologic experiments, are of value in suggesting the nutritional evaluation of proteins and the choosing of proteins which will be mutually supplementary.

The various methods of determining the relative values indicate that proteins of animal origin, i. e. milk, eggs, meat, poultry, fish and cheese, are superior in nutritive efficiency to most vegetable proteins. Furthermore, while these animal proteins are much alike in the value of their proteins, the same is not true of the vegetable proteins.[2] Thus, oats rank higher in biologic value than white wheat flour, but wheat is superior to corn in biologic value. Although beans, peas and lentils are considered of rather low biologic value, Everson and Heckert [3] have found that heating for forty-five minutes at 15 pounds pressure improved the nutritive value of mature soybeans, pinto beans, navy beans and kidney beans. Two varieties of peas were lowered in biologic value by the heating. In contrast, immature unheated peas appeared to supply an unusually high grade of protein. Peanuts rank high in biologic value. White wheat flour has been found to be decidedly lower in nutritive efficiency than the whole grain. Chick [4] has investigated the nutritive efficiency of the protein in three flours, from the same sample of grain, representing the 100 per cent whole grain, 85 per cent extractions and 75 per cent extraction. The third flour was that used for making ordinary white bread. The superior biologic value of the protein of the 100 per cent whole grain was striking and conclusive.

In spite of the lower biologic value of legumes and grains, it is well known that, when combined together in the diet, mutually supplementary relationships exist. Furthermore, it is recognized that a relatively small amount of animal protein will enhance considerably the value of the grains and legumes.[5]

From a practical point of view a quantitative evaluation of the supplementary relationship of proteins of mixed dietaries is needed. However, comparatively little is known about the biologic value of proteins making up a mixed diet. Recently Macrae, Henry and Kon [6] reported a study of the biologic value of mixed proteins in food served in Royal Air Force stations in England. The protein consumed per man daily varied from 83 to 101 Gm., and the proportion of the protein which was animal in origin ranged from 42 to 45 per cent. The results revealed that the diets had a high biologic value and a high degree of digestibility.

While more research is needed on the biologic value of the whole diet, it would appear that the current dietetic practice, that of providing one half of the protein from animal sources,[7] will insure a satisfactory factor of safety for the levels of protein intake recommended by the Food and Nutrition Board of the National Research Council [8] for the adult maintenance diet. In therapeutic diets, and in diets in which growth is a factor, it is a common practice to provide one half to two thirds of the protein from animal sources.

THE ORGANIZATION OF PROTEIN CONTAINING FOODS INTO PATTERNS OF FOOD INTAKE

The actual combining of protein containing foods into patterns of food intake may be organized most simply by noting the relative amounts of protein contributed by various food groups in a basic dietary pattern. From this basic plan it will then be possible to make adaptations in the protein intake suitable for various dietary prescriptions. An example of such a basic plan is presented in table 1.

8. Food and Nutrition Board, National Research Council: Recommended Dietary Allowances, Handbook of Nutrition, Chicago, American Medical Association, 1943, pp. 333-338.

This basic pattern of food intake might be outlined in innumerable meal plans. Two examples of possible combinations of these foods which would give the approximate protein intake listed in table 1 are given in table 2.

The basic pattern of food intake supplies approximately 60 per cent of the protein from animal sources and approximates also the recommended dietary allowances for minerals and vitamins outlined by the Food and Nutrition Board of the National Research Council.[8]

In addition to the valuable amounts of protein supplied by these foods, other nutrients are present which in some respects differ either in kind or in relative amount. For example, the milk contributes the major portion of calcium and phosphorus in the diet as well as the vitamins of the B complex. While 2½ ounces of cottage cheese would be an equivalent protein substitute for 1 pint of milk, the cottage cheese [9] would supply less than one tenth of the calcium, phosphorus, iron, vitamin A, thiamine and riboflavin supplied by the milk. Two and one-half ounces of American Cheddar cheese [9] would supply calcium equivalent to 1 pint of milk but would be much lower in the vitamins of the B complex. In this case the addition of liver or other glandular meat one or two times a week would be desirable to augment the iron, vitamin A and B vitamins in the diet; pork would enrich the thiamine intake. Eggs will supply a significant amount of vitamin A and iron. Legumes and whole grains will also contribute iron and vitamins of the B complex. Table 3 is a comparative table of nutrients in some of the protein containing foods.

TABLE 1.—*Basic Pattern of Daily Food Intake for an Adult Man (70 Kg.)*

Daily Food Intake	Approximation of Protein Content,* Gm.
16 oz. (1 pint) of fluid milk or 8 oz. of evaporated milk or 1½ oz. (5 tablespoons) of dried skim milk (1 serving [4 oz.] of milk pudding or ice cream may be approximately equivalent to 3 oz. of fluid milk)	15
3 oz. serving of meat or poultry or fish (cooked, edible portion) or 1½ oz. of soybean flour or 5 oz. (¾ cup) of cooked soybeans	18
1 oz. of American cheddar type cheese or 1 oz. of cottage cheese or 1 egg	6
3 oz. serving (one half cup) of cooked peas, navy beans, or lima beans, or ¼ cup cooked soybeans, or ⅔ oz. (1½ level tablespoons) of peanut butter	6
3 oz. serving (½ cup) of potatoes	2
Other vegetable—3 servings, of which 1 is green leafy or yellow	3
Fruits—2 servings, of which 1 is citrus or tomato	2
Six slices of bread, enriched or whole grain, or equivalent grain product (The approximte protein equivalent of one slice of bread is a 1 oz. (dry weight) serving of cereal or ½ cup of cooked spaghetti or noodles or 6 soda crackers or 1 small piece of cake or a 2 inch cube of cornbread or 3 graham crackers)	18
Total	70

* Meat, poultry, fish, cheese and nuts range between 10 and 30 per cent protein. Grain products (dry weight), fresh peas and beans contain between 7 and 15 per cent protein. Eggs contain approximately 12 per cent protein. Milk is about 3 per cent protein. For more detailed figures on the percentage composition of protein in foods see Chatfield, C., and Adams, G.: Proximate Composition of American Food Materials, Circular No. 549, U. S. Dept. of Agric., June 1940.

9. Cheese may be roughly divided into two classes, one in which the curd is formed through the action of the enzyme rennet, the other in which the curd is formed through the action of lactic acid. When the curd is formed through the action of rennet, as in American Cheddar cheese, the calcium is retained in the curd. When lactic acid is used to produce the curd, as in cottage cheese, the calcium is lost in the whey.

ADAPTATIONS OF THE BASIC PATTERN

Considerable elasticity is possible in the selection of protein foods from the basic pattern. From this basic plan, adaptations can be made suitable for the diet for the normal adult woman and the diet for pregnancy and lactation, for the needs of children and for high protein diets. Innumerable combinations of the foods on the basic plan are possible in making up satisfactory outlines for meals. However, only a few examples follow, since a specific dietary prescription will need to be integrated with the individual patient's food habits and his social and economic problems.

TABLE 2.—*Combinations of Foods Embodying Basic Pattern*

Breakfast	Noon Meal	Evening Meal
Citrus fruit 1 egg 2 slices of toast Coffee with milk or cream	Sandwich (peanut butter or cheese or meat) Vegetable salad 1 glass milk Fruit Cake	Meat Potato Cooked vegetable Mixed green vegetable salad 1 glass milk 1 slice bread Ice cream
	or	
Banana Whole grain cereal with milk 1 slice toast Coffee with milk or cream	Baked navy beans with pork Cabbage salad 1 glass milk Fruit custard 1 slice bread	Soup with crackers Chicken Sweet potato Cooked greens Grapefruit and orange salad Ice cream Cake 1 slice bread

Diet for the Adult Woman.—If 1 Gm. of protein per kilogram of body weight is used as a guide in setting up the level of protein in the diet, the dietary prescription may range between 50 and 75 Gm. of protein daily. A sample plan containing 50 Gm. of protein is given in table 4. Again, if less than 1 pint of milk is used in the dietary plan, it will be necessary to make an effort to replace not only the protein but also the calcium, phosphorus and vitamins of the B complex which milk supplies in major amounts.

TABLE 3.—*Nutrients in Certain Protein Containing Foods* *

Amount of Food	Protein, Gm.	Minerals: Calcium, Gm.	Minerals: Iron, Mg.	Vitamins: Vitamin A, I. U.	Vitamins: Thiamine, Mg.	Vitamins: Riboflavin, Mg.	Vitamins: Niacin, Mg.

* Tables of Food Composition Giving Proximate, Mineral and Vitamin Components of Foods, Committee on Food Composition of the Food and Nutrition Board, National Research Council March 1, 1944; Tables of Vitamin Losses in Cooking of Foods, June 1, 1944.
† ( ) Imputed values.

Diet for Pregnancy and Lactation.—Between 85 and 125 Gm. of protein may be recommended during this period, two thirds of which can easily be provided as animal protein. Extra needs for calcium, phosphorus, iron and vitamins have been indicated in the recommended dietary allowances of the Food and Nutrition Board of the National Research Council.[8] These extra needs can be supplied to excellent advantage simply by

adding milk to the basic pattern of food intake. Skim milk (defatted milk solids) or buttermilk may be used. When the patient is not accustomed to drinking milk, it may be desirable to provide suggestions for the use of milk in soups, desserts or flavored beverages. The most inconspicuous and, in many cases, the most acceptable way in which to add milk is in the form of dried milk. Approximately 1½ ounces (5 tablespoons) of dried skim milk (defatted milk solids) will equal

TABLE 4.—*Sample Plan Containing 50 Gm. of Protein*

	Protein, Gm.
1 pint of milk or milk equivalent	15
1 egg	6
2 ounces meat or poultry or fish	12
3 vegetables	3
2 fruits	2
4 slices of bread or equivalent grain product	12
Total	50

1 pint of fluid milk. This dried milk may be incorporated as a dry ingredient in the preparation of meat loaf, mashed potatoes, sandwich spreads, cooked cereals, hot breads, cookies, pastries or puddings with little difficulty. Also a palatable drink may be prepared by adding approximately 2½ tablespoons of dried skim milk to 1 glass (8 ounces) of fluid milk. This will provide approximately 15 Gm. of high quality protein per glass. In some parts of the country, dried milk may be obtained from the retail grocery store. In other places it may be necessary to depend on the courtesy of a bakery shop or hospital, or dairy.

Where cheese is substituted for milk, due attention must again be given in order to compensate for the large decrease in minerals and vitamins which would otherwise result. In this case the increased use of glandular meats and pork will be useful in augmenting these nutrients. Where milk or American Cheddar type cheese is not tolerated it is unlikely that the calcium and phosphorus will be met with other foods. Further attention will then have to be given to compensate satisfactorily for the protein and for other nutrients provided in milk. An example of a diet containing 100 Gm. of protein and meeting the recommended allowances of the Food and Nutrition Board of the National Research Council [8] for minerals and vitamins during lactation is presented in table 5.

Diet for Children.—Relatively more protein is recommended per unit of weight during the growth period. Recommended daily allowances vary between 40 and 100 Gm. of protein daily, depending on the age and "ideal" size of the child. The actual food selection will be similar to that outlined in the basic pattern of food intake, but the relative amounts of each food will vary during the child's developmental period. In younger children the 30 Gm. of protein provided in 1 quart of milk will insure a surplus of animal protein. With an egg daily and a small serving (2 ounces) of meat or cheese in addition, it will be possible to provide two thirds of the protein as animal protein on levels up to 65 Gm. of protein daily. When levels of 100 Gm. of protein daily for adolescent children are to be provided, a plan similar to the one suggested for pregnancy and lactation will supply the high levels of minerals and vitamins needed.

High Protein Diets.—When it is desirable to increase the protein content of the diet to levels as high as 150 Gm. daily, it may be difficult from the patient's point of view to increase further the protein containing foods enumerated on the basic pattern of food intake. The patient may have objections to the bulk, to the cost or to the flavor of these foods. In this case, use may be made of concentrated food sources of protein, particularly dried milk, which contains 25 per cent protein in dried whole milk and 35 per cent protein in defatted milk solids (dried skim milk). Other protein rich foods may be used, such as soybean flour, which ranges between 37 and 45 per cent protein, peanut flour, which may be 50 to 60 per cent protein, or dried yeast, which is approximately 45 per cent protein. Corn germ and wheat germ also have possibilities for use as valuable protein foods. Plain, dried gelatin contains 85 per cent protein.

As already mentioned, dried milk is one of the concentrated food sources of protein which may be used the most successfully. It may readily be incorporated as a dry ingredient in hot breads, cookies, cake, sandwich spreads, mashed potatoes, meat loaf, milk beverages and desserts, hot cereals and cream sauces, resulting in a decided increase in the protein intake. As stated previously, 2½ tablespoons of dried skim milk may be added to one glass (8 ounces) of fluid milk, thus providing 15 Gm. of high quality protein per glass of milk. This is a low cost product which supplies excellent quality proteins.

Soybean flour is another mild flavored, low cost product which can be successfully incorporated in cooking. Tabulations of comparative digestibility coefficients, amino acid analyses and results of growth promoting animal feeding tests all contribute to the conclusion that the protein of the soybean is of high biologic value. Soybean products are generally available at the present time and can be used in such prepared foods as pancake and muffin mixes, cereal products, macaroni and other paste goods, meat products, soups, breads and pastry products.[10] Approximately 500 tested recipes in both large quantity and family size have been collected from various agencies by the Diet Therapy Section of the American Dietetic Association.[11]

Since the production of peanut flour has increased as the result of priority allowances by the War Production

TABLE 5.—*Diet Containing 100 Gm. of Protein*

	100

Board, the use of this product is appropriate at this time.[12] As peanut flour contains approximately 50 to 60 per cent protein, an effective increase can be made in the protein intake with this product. It may be blended with cereals such as wheat, cornmeal, hominy grits, rolled oats, farina and various prepared dry cereals to increase their food value, and with cereal flour used in baked products. It can also be used as an extender and binder in meat loaves, sausage and

other meat products and as a base in dry soup concentrates.[13]

Another low cost product which has considerable merit is dried brewers' yeast, which contains approximately 45 per cent protein. The advantages of yeast, have been appreciated not only because it is an inexpensive source of recognized vitamins and protein but also because many experiments indicate that it contains essential factors that have not been isolated and recognized. Yeast makes pleasing combinations with syrup or peanut butter. It can also be used in baked products such as bread, cookies and doughnuts. Heller, McCay and Lyon [14] incorporated significant amounts of yeast successfully in meat loaves, stews, cheese dishes, baked beans and meat balls. These products were all accepted favorably in an industrial cafeteria serving 1,500 people daily. Carr [15] has published recipes for the use of yeast in home cookery.

Use may also be made of wheat germ which contains approximately 35 per cent good quality protein. It may be added directly to meat dishes, sandwich mixes, soups, cereal dishes or fruit mixtures. It has not been incorporated successfully in significant amounts in breads or cakes because of the change made in the texture of the baked product. Corn germ, another vegetable product with possibilities for becoming a valuable protein food, contains 20 per cent protein of a quality comparable to milk, meat and soybean protein.

Commercial products are available which combine dried milk, dried egg, wheat germ, whole grains and synthetic vitamins. Certain of these may be incorporated in milk beverages, thus being of especial value when liquid or soft diets are recommended. Bauman [17] has suggested a formula for a high protein beverage to increase the protein intake. Gelatin also may be incorporated in significant amounts in hot beverages or soups.

OTHER CONSIDERATIONS

In order to make the dietary plan acceptable to the patient it will be necessary to take into consideration the economic factors, the social and emotional problems of the individual patient and nowadays the rationing of foods.

An appraisal of protein containing foods in terms of cost usually shows that meat, poultry and fish are the most expensive items in the menu. While the current ceiling prices have a leveling effect on price at the present time, the usual factors of cost of production and marketing still need to be considered. The relative importance of these factors will vary in different parts of the country. Thus, if fish or poultry is more readily available they can be used, since these foods are of equal protein value with meat. At the present time the more select cuts of meat are scarce. More of the range fed, utility grade beef is available for civilian use. The utility grade beef contains less fat and a slightly higher percentage of protein than the choice cuts. Thus, on the basis of nutritive value no discrimination need be made against the lower grade meats or the less popular cuts. These meats are less tender, however. Tenderness may be obtained by a somewhat longer cooking period with moist heat, which brings about a hydrolysis of the collagen in the connective tissue to gelatin. To effect the greatest economy in both money and rationing allowances, it may be necessary to recommend to the patient that he (1) buy kinds and cuts of meats not used before, as less tender cuts and organ meats, (2) learn the suitable preparation for each cut, using low temperature cooking for all methods, (3) extend the flavor of meat with bland foods such as spaghetti, noodles and corn meal, (4) select recipes which combine the best elements of appetite appeal with nutritive value and (5) avoid kitchen waste, table waste and waste from improper storage. Furthermore, it is not necessary to use large amounts of meat even in the high protein diet.[18] Adequate substitutions may be made for meat by the selection of equivalent amounts of other protein containing foods. Thus the equivalent of 1 ounce of meat might be 1 ounce of poultry or fish, or 1 egg, or 1 glass of milk, or 1½ tablespoons of peanut butter or 1 serving of legumes. In addition such low cost, unrationed products which are concentrated sources of protein may be used advantageously as dried milk, soya products, peanut flour, dried brewers' yeast and wheat or corn germ. At the present time it is not difficult to obtain adequate amounts of protein containing foods from the unrationed list.

Among the less expensive protein containing foods, milk is the most important not only in terms of good quality protein but in terms of other nutrients as well. Furthermore, the valuable supplementary protein relationships between milk and vegetable proteins will enable the patient to make greater use of the low cost legume and grain proteins with safety.

The patient's acceptance of protein foods to which he has not been accustomed will depend on satisfactory adaptations of the dietary plan to the different national, regional, religious or racial backgrounds of each patient.[19] Furthermore, the instructions of the food clinician become increasingly effective as psychologic factors are taken into account in teaching nutrition. Behavior in relation to food is often an interplay between the physical and the emotional life. As in other phases of medicine, the patient must be considered as a "whole" if the therapy is to be effective.

ENZYMIC DETOXICATION OF POISON IVY

During recent years Hill,[1] Mason [2] and others have isolated and identified certain skin irritants from poison ivy, poison oak and related plants. Keil [3] has shown that these substances are phenols or catechols characterized by long unsaturated side chains attached to the phenolic ring. The toxic properties are in large part due to the presence of OH groups in this ring. On exposure to air a slow auto-oxidation of these toxic groups takes place. This has suggested that a logical method of preventing or treating poison ivy dermatitis would be by the use of strong oxidents such as ferric chloride and potassium permanganate.

In their search for a less irritating therapeutic agent, Sizer and Prokesch [4] of the Massachusetts Institute of Technology tested whether or not a similar oxidative detoxication can be effected by the use of enzymes. Since phenolic oxidases are not highly specific,[5] Sizer selected mushroom tyrosinase for his oxidation tests. The isolated toxic principle of poison ivy was mixed with tyrosinase and the rate of oxidation determined by measuring the rate of oxygen consumption in the Barcroft respirometer. The mixture consisted of 1 cc. of poison ivy extract, 0.1 cc. of tyrosinase and 3.2 cc. of buffer (p_H 7.3). The consumption of oxygen proceeded rapidly to 60 per cent completeness during the first four hours and with increasing slowness for five days, when the oxidation was practically complete. Additional evidence that the toxic molecules had undergone catalytic oxidation was furnished by a gradual darkening of the color of the mixture.

The dermatitis producing properties were greatly reduced. This was shown by parallel patch tests on both human and sensitized [6] guinea pig skin. In all cases a much more severe dermatitis was noted in the control area covered with the untreated toxin than in the area covered with the oxidized toxin. In many cases dermatitis was not noted with the oxidized product.

The therapeutic efficiency of tyrosinase was tested by applying simultaneously to human skin a poison ivy concentrate and tyrosinase, control test being made with boiled or inactivated tyrosinase. In all cases the area treated with the active enzyme gave much less dermatitis than the control, indicating sufficiently rapid oxidation to be of therapeutic promise. If equally successful results can be obtained by applying tyrosinase some time after the toxicant has reached the skin or, preferably, after erythema has developed, then a new method of treating poison ivy dermatitis will be available. Clinical tests of the latter possibilities are now in progress.

NUTRITION AND CANCER

The nutritional state of the patient assumes an important role in curing disease. In both experimental and spontaneous tumors the influence of energy intake, fat consumption per se, protein content of the diet and deficiency of certain vitamins have been shown to influence the course of development of the tumor. Many investigations have shown that mere restriction of food consumption in animals will reduce the incidence of both spontaneous and artificially induced tumors. Tannenbaum [1] has demonstrated with statistics gathered from the life insurance companies that an increased incidence of cancer occurs among persons who were overweight at the time the insurance policy was issued. On the basis of such evidence Potter [2] has even advocated ample exercise and a minimum food consumption as a measure for the prevention of human cancer.

Recently Morris [3] has shown that in mice on a restricted calory regimen, so that the weanlings did not gain weight and adult animals lost up to 45 per cent of their weight, the incidence of spontaneous mammary tumors was reduced from a control value of 38 per cent to 0 per cent. However, he noted that this diet also inhibited estrus and delayed mammary development. With regard to ample exercise and the number of transplanted tumors which developed, Kline and Rusch [4] have not observed difference between rats which had been forced to exercise and the controls.

Diets which are deficient in protein also influence the occurrence and growth of tumors. White and Andervont [5] have shown that there is a lowered incidence of spontaneous mammary tumors in mice on either a

lysine or cystine deficient diet. Here again the mammary glands were infantile in development even in mice old enough to be mature. Also there have been studies showing that rats on diets deficient in biotin or pyridoxine show a decreased incidence of tumor formation.

The important question raised by Morris is "To what extent would the dietary regimens found effective in delaying or preventing mouse mammary cancer be effective in delaying or preventing the same disease in man." He concludes that the diets that seem to reduce the incidence of cancer are too drastic, even if they could be applied, to be of any practical value for the prevention of human cancer. Also the effect of exercise was not adequately investigated even in animals, so that definite conclusions cannot be drawn concerning its applicability to human cancer.

Current Comment

VITAMIN C IN HAY FEVER

About three years ago the administration of vitamin C was suggested for the treatment of hay fever and other allergic conditions. Generally this therapy has been viewed with skepticism, but nevertheless some have given it fair trial. Most recent of the reports is that of Friedlaender and Feinberg,[1] who found that hay fever patients have a normal level of vitamin C; although large doses of this vitamin produce saturation blood levels, they do not change the course of hay fever or asthma. In view of this and previously published evidence vitamin C therapy for hay fever and other allergic conditions may be considered useless and wasteful.

RADIOCYSTITIS

Chronic actinic injury following the therapeutic use of roentgen rays and radium is most thoroughly studied and most often noted in the skin, but it occurs not infrequently in internal organs incidentally exposed to radiation. The delayed and insidious development of such reactions, obscuring the causal interrelations, and the inaccessibility of the internal organs to direct inspection are responsible for the smaller degree of attention these lesions have received. Since the urinary bladder is situated within the beam of roentgen and radium rays used for the treatment of neoplastic and other conditions of the uterus, prostate, bladder and rectum, acute and late actinic injuries to this organ are relatively common.[1] Dean [2] noted that all patients receiving more than 3,500 mghrs. of radium therapy, or its equivalent by high voltage roentgen rays, would very likely develop injury of the bladder from the therapy itself, that 27 per cent of all patients treated in this region with actinic rays required prolonged care for vesical distress and that 14.5 per cent had serious lesions of the bladder, such as ulcers and necroses. The therapeutically important actinic injury to the bladder is of the delayed type, appearing six to twelve months after treatment, or the late type, one to nine years after treatment. Such injury is associated with anatomic changes in the vesical wall, namely bullous edema, congestion, telangiectasis, superficial or deep ulcerations, calcareous incrustations and deposits, and causes severe pain, burning sensation on urination, polyuria, tenesmus and hematuria. The functional and anatomic phenomena may resemble closely those in tuberculosis or primary or secondary cancer of the bladder. Biopsy may be necessary at times for differential diagnosis. In the bladder are degenerative and proliferative changes in the epithelium, with swollen and often grotesquely distorted cells, forming not infrequently syncytial masses with large nuclear bodies. There occur ulcerative defects and fibrosis of the submucosa with telangiectasis. Since obliterative endarteritic lesions are not prominent they do not explain the degenerative lesions. Experimental studies on roentgen cystitis in dogs [3] have shown that the injured bladder tends to become infected by fecal bacteria. This infection is refractory to the usual treatment. For this reason patients subjected to actinic therapy involving the bladder should be kept under close urologic supervision so that adequate therapeutic measures may be started on the first signs of radiocystitis, as the control of the fully developed condition is usually protracted and often unsatisfactory.

ANTIBIOTICS

The terms "antibiotics" and "antibiotic effect" were suggested by Waksman and his co-workers in the Department of Microbiology, New Jersey Agricultural Experiment Station, Rutgers University. Waksman, Horning and Spencer [1] isolated sixteen strains of Aspergillus fumigatus and three strains of Aspergillus clavatus from stable manure. These two organisms produced, when grown on synthetic mediums, active substances that differed greatly in their chemical nature and biologic activity. They were designated by the authors as "fumigacin" and "clavacin" respectively. Clavacin was found to be particularly active against gram negative bacteria. The distinguishing characteristic of this substance is that it is both bacteriostatic and bactericidal. Subsequently these substances were crystallized [2] and their chemical nature determined. When gliotoxin, present in fumigacin, is removed, the

purified substance retains its antibacterial activity and only a limited toxicity to animals. At about the same time the English workers Chain, Florey, Jennings and Williams [3] isolated the same substance from a strain of Aspergillus fumigatus and described it as helvolic acid. These investigators believed that helvolic acid was not identical with fumigacin because of certain well defined chemical differences, in particular that of containing nitrogen. The nitrogen content is presumably gliotoxin, mentioned by Waksman. However, Waksman believes that helvolic acid is identical with fumigacin in chemical composition, anti-bacterial action and in vivo activity. He also points out that the isolation of claviforme by Chain and his associates was announced simultaneously with that of clavacin. Waksman stresses that much confusion has arisen in this field from the fact that various micro-organisms are capable of producing the same type of antibiotic substance and that many organisms are capable of producing more than one type of substance. Thus Aspergillus fumigatus has the capacity of forming four different antibacterial compounds—spinulosin, fumigatin, fumigacin and gliotoxin. The three different organisms Aspergillus clavatus, Penicillium claviforme and Penicillium patulum produce the same antibiotic substance. Research has revealed a high degree of cell activity by various antibiotic substances on different bacteria. As pointed out by Schatz and Waksman,[4] Mycobacterium tuberculosis is subject to bacteriostatic action of a variety of antibiotic substances, streptomycin, isolated by them, being promising. This substance is effective also against various related organisms, namely Erysipelothrix and Actinomyces griseus, first described by Schatz and Waksman.

PENICILLIN AS A FOOD PRESERVATIVE

In pasteurization of milk and nonpressure canning of fruits and vegetables all vegetative forms of bacteria are usually killed. The residual bacterial contaminants usually consist solely of heat resistant spores. On germination these spores are the main source of toxins and other forms of food spoilage. Since the use of strong chemical antiseptics is not feasible with food products, Curran and Evans [1] of the Division of Dairy Research, U. S. Department of Agriculture, tested the possible efficacy of penicillin as a food preservative (sporicide). Washed bacterial spores, entirely free from vegetative cells, were suspended in sterile water or milk. The suspensions were heated to 95 C. for fifteen minutes to precondition the spores for later germination. Previous tests [2] had shown that many aerobic spores remain latent for a long time without such heating. A measured amount of pencillin was then added to each mixture and the mixture incubated at the optimum temperature for germination. At the end of five to twenty-seven hours' incubation the residual penicillin was inactivated by the addition of penicillinase. The mixtures were then plated. The difference between the number of viable spores thus determined and the original spore count was taken as a measure of sporicidal activity. In a typical test an initial milk count of 256 Bacillus subtilis spores per cubic centimeter was reduced to 1.6 spores per cubic centimeter by the end of five hours and to 0.04 spore per cubic centimeter by the end of twenty-seven hours. Five Oxford units of penicillin per cubic centimeter was used in this test. Similar though less rapid sporicidal action was recorded with the spores of all other aerobic bacteria thus far tested. Effect on anaerobic spores has not yet been reported. The extraordinary effectiveness of pencillin in low concentrations against bacterial spores, together with its nontoxic nature, led Curran to suggest the use of penicillin in numerous nonmedical fields, including that of food preservation. Relatively inexpensive crude penicillin presumably would be satisfactory for such uses.

IN VITRO GROWTH OF THE MALARIA PARASITE

The growth of the infective agent in vitro is an important achievement in the investigation of a disease. Whether the emphasis is immunologic, biochemical, nutritional or chemotherapeutic, growth of the parasite in vitro eliminates many secondary or masking effects which the body of the host produces. Recently Ball and his associates [1] have grown the monkey malaria parasite Plasmodium knowlesi in vitro; the medium consists of one-third whole blood and two-thirds purified nutrient solution. Under these conditions it is possible to have the number of organisms increase three or four fold in a twenty-four hour period. With this new method of attack the distribution of phosphorus among the various types of compounds and the oxygen consumption of the organism were determined. Stimulated by the early success, work is in progress on the growth of the human malaria parasite under these conditions. The increasing importance of this disease in the nation's health emphasizes the need for more knowledge regarding the life processes of the infective agent; hence the foregoing experimental device merits further attention.

FOURTH OF JULY FIREWORKS ACCIDENTS

For many years annual summaries of the injuries from fireworks occurring throughout the nation in celebration of the Fourth of July were published in THE JOURNAL. These summaries were influential in bringing about legislation in many states which sharply reduced the frequency of these unnecessary accidents. The fine record of recent years in this respect should be continued. Every effort should be made to curb the use of fireworks on this holiday in order to keep the inevitably attendant injuries at a minimum.

MEDICINE AND THE WAR

ARMY

GERMANY'S TECHNIC IN SURGERY LAGGING

Germany, once the world's acknowledged leader in surgery and medicine, is twenty years behind American methods in the handling and healing of war wounded, according to Col. Edward D. Churchill, Allied Mediterranean forces' surgical consultant, who recently inspected the wounded in former German hospitals. A German army colonel indicated that he regarded the outcome of wounds in this war to be identical with conditions he observed in the first world war. American recoveries, on the other hand, improved phenomenally, such as field operating tents up at divisional clearing stations, the highly developed use of blood transfusions and the high standard of antisepsis in the field.

In the six German hospital areas inspected by Colonel Churchill he found that of forty serious chest wounds picked at random thirty-seven showed infection, while the American patients' average was well below 10 per cent. For blood transfusions the Germans used an antiquated syringe type apparatus discarded years ago by the Americans. The Germans had not realized the possibilities of transfusion and would not believe, until the Americans gave a demonstration, that one man could successfully receive more than 600 cc.

The fundamental difference found between the American and the German system is that the Americans have a systematic, continuous routine from the moment of wounding until the highest possible degree of restoration to health. Infected chest wounds, which after the first world war left hundreds permanently hospitalized with great gaping wounds, can now be handled so that within a few weeks the men are completely restored with normal respiratory systems. The Germans' methods, on the other hand, were characterized by a lack of direction or any general and definite policy in professional methods. Colonel Churchill stated that individual surgeons carried on "just about as they pleased" and field surgeons were inclined to pass over extremely serious cases with the idea that the injured men would die anyway.

LOCAL APPLICATION OF CRYSTALLINE SULFONAMIDES DISCONTINUED

The War Department Technical Bulletin of Medicine (TB MED 147), March 1945 (distributed to general and field hospitals and other medical units), announced the general policies regarding the local use of chemotherapeutic agents. Experience in wound management justifies the abandonment of local use of any chemical agent in a wound for its supposed antiseptic effect in the prevention or treatment of infection. The practice of routine local application of crystalline sulfonamides to wounds as an emergency aid measure and prior to initial wound surgery will be discontinued. The local application of these compounds to wounds not involving serous cavities following wound surgery will also be discontinued, and their local use in wounds involving serous cavities is not recommended.

ARMY AWARDS AND COMMENDATIONS

Colonel Cornelius P. Rhoads

Award of the Legion of Merit was recently bestowed on Col. Cornelius P. Rhoads, formerly of New York. He was cited for the development of methods for combating poison gas and other advances in chemical warfare. Dr. Rhoads was head of the Chemical Warfare Service's Medical Division from June 1943 to April of this year, and he established the Toxicological Research Laboratory at Edgewood Arsenal, Md., and the Medical Research Laboratory at the Dugway Proving Ground, Tooele, Utah. "He developed new methods of diagnosis and treatment for relief of injuries due to toxic chemicals and perfected a compound to counteract the effects of blister gas. At Bushnell, Fla., and San Jose Island, Canal Zone, he established medical testing stations. He also developed equipment for detecting the presence of war gases in air, food and water." Dr. Rhoads graduated from Harvard Medical School, Boston, in 1924 and entered the service June 15, 1943.

Captain Douglas Lindsey

The Silver Star was recently awarded to Capt. Douglas Lindsey, formerly of Minden, La., "for gallantry in action against the enemy in Germany. On . . . during the assault across the . . . River, Capt. Lindsey, battalion surgeon, braved heavy small arms and artillery fire to reach and administer medical treatment to a helpless wounded rifleman. His courageous conduct and professional skill throughout the early stages of this attack were material factors in the prompt treatment of casualties. Capt. Lindsey's exemplary devotion to duty under hazardous conditions reflects great credit on himself and the military service." Dr. Lindsey graduated from Yale University School of Medicine, New Haven, Conn., in 1943 and entered the service Jan. 12, 1944.

Captain Edwin S. Kessler

The Bronze Star was recently awarded to Capt. Edwin S. Kessler, formerly of Cleveland Heights, Ohio, for "heroic achievement in connection with military operations against the enemy during his division's historic reduction of Metz." He directed operations of a battalion aid station in a highly distinguished manner, despite continuous exposure to enemy fire, and his heroic performance of duty was instrumental in saving many lives. Dr. Kessler graduated from Western Reserve University School of Medicine, Cleveland, in 1942 and entered the service July 16, 1943.

Major Sylvan W. Simon

Major Sylvan W. Simon, formerly of Chicago and now with the Air Service Command in Italy, was recently awarded the Bronze Star after he led his medical detachment in stamping out a civilian smallpox epidemic before it reached the thousands of combat airmen of the 15th Air Force who were on duty at nearby airfields. Dr. Simon graduated from Rush Medical College, Chicago, in 1926 and entered the service in October 1940.

Captain John J. Goldsberry

Capt. John J. Goldsberry, formerly of Worcester, Mass., recently received a letter of commendation from the Surgeon General for his origination of the basic idea of a furlough pamphlet as an aid in the prevention of venereal disease in soldiers while on furlough. The commendation read "To the knowledge of this office, Capt. Goldsberry was the first station venereal control officer to organize an effective program aimed at reducing the incidence of venereal disease acquired on furlough and is to be commended for his initiative and originality." Dr. Goldsberry graduated from Howard University College of Medicine, Washington, D. C., in 1926 and entered the service May 12, 1941.

Major James J. Whitsitt

Major James J. Whitsitt, formerly of Houston, Texas, who was with the Airborne troops in the Normandy invasion, was recently awarded the Bronze Star, the Presidential Unit Citation and the Purple Heart, the latter for mortar fire wounds in the leg and thigh. He is now in Germany. Dr. Whitsitt graduated from the University of Tennessee College of Medicine, Memphis, in 1932 and entered the service Aug. 18, 1942.

Major E. Charles Powell Jr.

The Bronze Star and the Meritorious Service Unit Plaque was recently awarded to Major E. Charles Powell Jr., formerly of Goldsboro, N. C. The citation accompanying the Bronze Star read "For meritorious service in connection with military operations against the enemy in Belgium and Germany, November 18, 1944 to March 5, 1945. As regimental surgeon during this period Major Powell, by his display of outstanding administrative ability, technical knowledge and loyalty, supervised the treatment and evacuation of wounded and sick personnel of his regiment under the difficulties of combat conditions and adverse weather in a manner which has insured prompt and efficient medical care. The preventive measures instituted by him during the months of winter warfare were largely responsible for the reduction of frostbite casualties within his unit. The skill, exemplary action and commendable conduct exhibited by Major Powell reflect high credit on himself and the military service."

The citation accompanying the Meritorious Service Unit Plaque read "The Medical Detachment, 334th Infantry, is awarded the Meritorious Service Unit Plaque for superior performance of duty in the accomplishment of exceptionally difficult tasks, Nov. 19, 1944 to March 18, 1945. During this period the members of the unit, maintaining a high standard of discipline and displaying courage despite heavy enemy fire and adverse conditions, administered medical aid and evacuated casualties from the field of battle in a manner which resulted in saving the lives of many soldiers and contributed materially to the success of the regiment's military operations. The brave, unselfish action and commendable conduct of the members of the Medical Detachment, 334th Infantry, reflect high credit on the unit and the armed forces of the United States." Dr. Powell graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1935 and entered the service Sept. 15, 1940.

Major Samuel H. Flowers

The Bronze Star was recently awarded to Major Samuel H. Flowers, formerly of Middlesboro, Ky., "for meritorious service in direct support of combat operations during the period Feb. 10, 1944 to Nov. 20, 1944. Serving Air Force combat units, Major Flowers as surgeon of this hospital (34th Field Hospital) was on call twenty-four hours a day to administer surgical aid to wounded personnel of returning combat crews. Through his devotion to duty and his unstinting efforts beyond the call of duty, Major Flowers has contributed substantially to the combat efficiency of the units served by this organization, and his outstanding service reflects great credit on himself and the Armed Forces of the United States." Dr. Flowers graduated from the University of Louisville School of Medicine in 1931 and entered the service June 20, 1943.

Lieutenant Colonel Noah Barysh

Lieut. Col. Noah Barysh, formerly of New York City, was recently awarded the Bronze Star. The citation accompanying the award read "For meritorious achievement in connection with military operations against the enemy in the North African theater of operations from Nov. 8, 1942 to May 17, 1943. The professional skill, personal courage and untiring energy with which Colonel Barysh performed his duties as regimental surgeon contributed immeasurably to the prompt and efficient treatment of battle casualties throughout the North African campaign. Colonel Barysh's outstanding devotion to duty reflects great credit on the Army of the United States." Dr. Barysh graduated from Rush Medical College, Chicago, in 1933 and entered the service Dec. 21, 1940.

Lieutenant Colonel Julius Sandhaus

Lieut. Col. Julius Sandhaus, formerly of Lancaster, Pa., was recently awarded the Bronze Star for developing what was originally designed as a 40 bed crash ward at an Air Service Command depot in England into a modern, fully equipped hospital, capable of meeting the medical needs of an American city of 35,000 people. Dr. Sandhaus graduated from Jefferson Medical College of Philadelphia in 1936 and entered the service in January 1941.

Captain Harvey L. Rittenhouse

The Bronze Star was recently awarded to Capt. Harvey L. Rittenhouse, formerly of Albany, N. Y. The citation read, in part, "Capt. Harvey L. Rittenhouse, . . . while serving with the Army of the United States, distinguished himself by meritorious service in France. Captain Rittenhouse has been fulfilling his combat mission as medical officer in charge of Ward Section, Second Platoon, from the time the company began operations under combat conditions, Aug. 10, 1944, to the present. During this time he has repeatedly demonstrated his skill and devotion to duty, which has resulted in superior medical service to the patients." Dr. Rittenhouse graduated from the College of Medical Evangelists, Los Angeles, in 1943 and entered the service Aug. 7, 1943.

Colonel Julius M. Blank

The Legion of Merit was recently awarded to Col. Julius M. Blank, formerly of New York City, "for exceptionally meritorious conduct in the performance of outstanding service in New Guinea from Oct. 7, 1942 to April 3, 1943." The citation accompanying the award stated that Colonel Blank "planned, recommended and executed policies for American medical supply, sanitation, hospitalization and evacuation and greatly assisted in the coordination with Allied forces of these matters, which were very important in this area." Dr. Blank graduated from Long Island College of Medicine, Brooklyn, in 1916 and entered the service July 17, 1942.

Major George L. Seifert

The Air Medal with an Oak Leaf Cluster was recently awarded to Major George L. Seifert, formerly of Philadelphia, "for meritorious achievement while participating in sustained operational flight missions to areas where hostile contact was probable and expected." Dr. Seifert graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1934 and entered the service in August 1942.

Captain Robert W. Leibold

Capt. Robert W. Leibold, formerly of Pittsburgh, was recently awarded the Bronze Star for meritorious service in Germany. During a series of operations against the enemy he assisted materially in the treatment, care and evacuation of a large number of wounded men. Dr. Leibold graduated from the University of Pittsburgh School of Medicine in 1941 and entered the service Aug. 1, 1942.

Captain Jesse B. Caldwell Jr.

Capt. Jesse B. Caldwell Jr., formerly of Cramerton, N. C., was recently awarded the Bronze Star "for meritorious service in connection with military operations against an enemy of the United States in France, Belgium, Luxembourg and Germany from Nov. 6, 1944 to March 22, 1945." Dr. Caldwell graduated from McGill University Faculty of Medicine, Montreal, in 1941 and entered the service July 1, 1942.

Major John S. Bralliar

Major John S. Bralliar, formerly of Rockford, Ill., and now commanding officer and chief surgeon of a portable surgical hospital in the Philippines, was recently awarded the Bronze Star "for meritorious service on Luzon." Dr. Bralliar graduated from the University of Tennessee College of Medicine, Memphis, in 1939 and entered the service Dec. 4, 1940.

Captain Paul A. Nierling

Capt. Paul A. Nierling, formerly of Cresco, Iowa, was recently awarded the Bronze Star for meritorious achievement in connection with military operations against the enemy at Luzon. Dr. Nierling graduated from the State University of Iowa College of Medicine, Iowa City, in 1932 and entered the service Nov. 3, 1942.

Captain Lyle B. Putnam

Capt. Lyle B. Putnam, formerly of Wichita, Kan., has been awarded the Silver Star, a Presidential citation and the Purple Heart. Dr. Putnam graduated from the University of Kansas School of Medicine, Kansas City, in 1936 and entered the service in June 1942.

NAVY

NAVY INTERN TRAINING OUTLINED IN NEW BOOKLET

A booklet entitled "Essentials of Internship and Residency-Type Training in United States Naval Hospitals" (Navmed 762) has been prepared by the Professional Division, Bureau of Medicine and Surgery, and is now available for general distribution. This outline was initiated by the Honorary Consultants to the Surgeon General of the Navy. It describes the educational standards and program including uniform hospital libraries necessary to maintain official approval for internship training and for residency-type training in the specialties.

Its foreword by Vice Admiral Ross T. McIntire, Surgeon General of the Navy, states that "junior medical officers assigned to specialty services in naval hospitals will not be termed residents, nor will such services be designated formally as residencies. However, as far as the educational program for such services and assignments conforms with approved residency-type training standards, residency credits will be obtainable by junior medical officers for time engaged in such work while in naval service."

It is possible also for many medical officers assigned to larger dispensaries and other activities to obtain similar residency credits before the American colleges and the American boards.

NEW BRANCHES CREATED IN PROFESSIONAL DIVISION

Vice Admiral Ross T. McIntire, Surgeon General of the Navy, recently approved a reorganization of the Medicine and Surgery Branch of the Professional Division creating two branches of the specialties, namely a Medicine Branch and a Surgery Branch. Capt. F. R. Hook (MC), U.S.N., will head the Surgery Branch, and Comdr. J. R. Miller (MC), U.S.N.R., will head the Medicine Branch. The latter branch is composed of a General Medicine Section and a Tropical Medicine Section.

Functions of the Professional Division are defined as follows: "The Professional Division shall (*a*) consult with medical activities ashore and afloat in order to determine the professional needs and problems arising in the field; (*b*) study, evaluate, advise and make recommendations on the professional needs, policies, standards, practices and performances of the Medical Department, particularly as these relate to medicine, surgery, neuropsychiatry, rehabilitation and hospitalization, and (*c*) maintain liaison with such other military and civilian agencies as may be required in the prosecution of the functions of this division. The term 'professional' as used is interpreted to include all phases of clinical practice as well as the technical services and facilities required to make such practice effective."

HOSPITAL CORPS OFFICER AWARDED LETTER OF COMMENDATION

A Letter of Commendation was recently awarded to Lieut. (jg) William A. Breathwit (HC), U.S.N. The citation, which was signed by Admiral Harold R. Stark, U.S.N., read "Your performance of duty while serving at a large naval base hospital in southern England prior to and after the invasion of the coast of France in June 1944 has been brought to my attention. You were instrumental in the organization and efficient operation of this hospital from its very inception. During the formative period you carried the responsibility for much of the detail work involved in the transfer of the hospital from the U. S. Army. You effectively assisted in the organization of the facilities established for the reception and evacuation of casualties. In addition to your regular duties, which were complex and skilfully carried out, you were invariably present during the admission and evacuation of large groups of casualties, to render what services you could in the interest of efficiency. Your work in the personnel department and in charge of the expeditious and correct reporting of casualties was of high order and contributed materially to the successful work of the hospital. For your devotion to duty and administrative ability you are hereby commended. This commendation carries with it the privilege of wearing the commendation ribbon."

RHEUMATIC FEVER UNIT ESTABLISHED

The Secretary of the Navy has approved a 400 bed expansion of hospital facilities and the establishment of a rheumatic fever research unit at the U. S. Naval Hospital, Dublin, Ga. Commissioned earlier this year, the hospital at Dublin is of permanent type construction, as will be the buildings under the expansion program. However, the building to house the research unit will be a temporary structure. It is slated to begin at once and to be completed about August 30. The hospital at Dublin is used almost exclusively for rheumatic fever cases, and officials in charge of the research project there will work closely with the hospital authorities.

ESTABLISHES ASSISTANT FOR DENTISTRY

Vice Admiral Ross T. McIntire, Surgeon General of the Navy, recently announced the establishment of the post of assistant for dentistry in the Bureau of Medicine and Surgery under whom the functions of the Dentistry Division and the Office of Inspector of Dental Activities will be carried on in accord with a new organizational plan for dental activities in the bureau. Rear Admiral Alexander G. Lyle (DC), U.S.N., has been named the assistant for dentistry and has served for some months in the bureau as inspector of dental activities.

The functions of the assistant for dentistry were defined as follows: The assistant for dentistry shall be responsible for the performance of all dental functions but shall adopt no major policies, methods or procedures without the approval of the chief of the Bureau of Medicine and Surgery. The assistant for dentistry may have on his personal staff such other personnel as may be required to assist him in the general administration of his duties.

The organizational plan announced included, besides establishment of the assistant for dentistry, a Dental Professional Office, a Dental Personnel Office and a Dental Inspections Office.

WAVE HOSPITAL CORPS TRAINING SCHOOL

Camp Moffett, one of the larger units of the Naval Training Center at Great Lakes, Ill., is being converted for use as a Hospital Corps School to accommodate 1,500 Waves under plans approved by the Bureau of Medicine and Surgery. It is expected that conversion will be completed in time to take the first increment of recruits from Hunter College the latter part of July.

Beginning with the first class, the Hospital Corps will receive 500 girls each two weeks for training. One hundred and twenty-five of these will be given eight weeks' training at Bethesda and 375 will be sent to the new unit at Great Lakes for their schooling. At the end of an eight week period both schools will have reached their full capacity: 500 at Bethesda and 1,500 at Great Lakes. This schedule is slated to continue through a period of ten months, at the end of which time the Hospital Corps will have trained 10,000 additional Waves.

NAVY AWARDS AND COMMENDATIONS

Commander DeWitt K. Burnham

The Legion of Merit was recently awarded to Comdr. DeWitt K. Burnham, formerly of San Francisco. He was cited for "exceptional performance of duty, clearly above that normally expected" while on duty in the South Pacific. Through his "untiring efforts in maintaining sanitary standards, he has reduced the incidence of sickness and disease to a remarkably low degree and provided necessary medical attention for all personnel at the base," the citation said, adding that Commander Burnham had instituted a "highly efficient system for handling large numbers of patients and casualties from hospital ships." Dr. Burnham graduated from Stanford University School of Medicine, San Francisco, in 1930 and entered the service Dec. 18, 1941.

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

June 18, 1945.

Possible Release of Doctors and Dentists from Armed Forces

Major Gen. George F. Lull, Deputy Army Surgeon General, has estimated here that 2,000 to 3,000 doctors and several hundred to 1,000 dentists should be available for discharge from the Army by the end of this year. General Lull said the peak load on the Army Medical Corps will be reached in the fall. He explained that the wounded must still be transported home from Europe and soldiers scheduled for redeployment or discharge must be given physical examinations. He expects that most of the doctors and dentists released will return to civilian practice. The Veterans Administration has sought medical men, but its most urgent requirements were met by assignment of about 300 medical officers to the agency, he said. Most of these were assigned last year on active status, and 112 had previously served with the Veterans Administration. However, no Army doctors are now being assigned to the Veterans Administration unless they desire it. General Lull said that "as the size of the Army is reduced under the partial demobilization plan, it will be possible to release certain numbers of doctors and dentists. However, the shrinkage in the number of medical officers will not be in proportion to the reduction of the Army as a whole, since the Army will still have many wounded in hospitals. Moreover, we never filled our quota of 48,000 doctors, as only about 45,000 were obtained. Dental officers number about 15,000. We probably can release 2,000 to 3,000 medical officers and a proportionate number of dental officers by the end of the year."

General Bradley to Take Veterans Administration Post August 11

Although he conferred with members of the House Veterans Committee on proposed veterans' legislation and has already started a study on how to correct shortcomings in the administration of veterans' hospitals, General Bradley has returned to Europe to serve in the absence of General Eisenhower. He will take over as Veterans Administration chief about August 11. Meanwhile Committee Chairman Rankin has reported that hearings on proposed legislation to reorganize the medical staff of the Veterans Administration will be postponed until General Bradley returns. "We will continue with the investigation to have a full record for General Bradley and the committee," he said. "It will serve as a basis for corrective legislation." Before adjournment the committee heard Col. Louis Verdel, manager of the veterans' hospital at Northport, N. Y., where it was alleged that the Army had assigned physically and mentally unfit soldiers to attend mental patients, deny that Northport was the worst hospital in the service. He claimed that two of five army doctors attached to the institution were on prolonged sick leave, one of them diagnosed as neurotic by army examiners. "Maybe we'd better investigate the War Department," said Mr. Rankin. "I bitterly resent the War Department's attitude toward these veterans' hospitals."

Naval Medical Chief Lauds Care of Wounded on Okinawa

Vice Admiral Ross T. McIntire informed civilian and service personnel of the Navy Bureau of Medicine and Surgery that navy medical men caring for troops wounded on Okinawa "have lacked nothing" in supplies and equipment. His comment was made during presentation of awards to personnel for beneficial suggestions and achievement.

Capital Notes

Sister Elizabeth Kenny told a press conference that the purpose of her two months trip to England and Sweden was to "stimulate research" in infantile paralysis in these two countries rather than to set up clinics.

Gallinger Hospital plans to take an active part in the postgraduate education of doctors returning from the armed forces, Dr. Daniel L. Seckinger, acting superintendent, announces.

District of Columbia's new mental hygiene clinic has reached a stalemate through the sudden resignation of Dr. John F. Owen of Raleigh, N. C., after only a month, because of inadequate office and clinic space provided.

Council on Medical Service and Public Relations

PREPAID MEDICAL CARE NEWS

Washington Medical and Hospital Service Plan

In reviewing the history of medical bureaus in Washington it has been noted that in 1931 and 1932 several service bureaus were started in counties throughout the state where population would warrant. As there was a close relationship of one county bureau to another and a reciprocal agreement between their physician members, the Washington State Medical Bureau was set up as a coordinating and parent body. While the local county bureaus, of which there are now seventeen, exercise certain local autonomy to meet the needs of their respective communities, the plan as a whole is statewide and is referred to as the "Washington Plans." It is under the supervision and guidance of the Washington State Medical Association and is administered by the Washington State Medical Bureau.

Medical service bureaus have carried out the service policy, and in order that they may be legal in every respect to meet requirements of the insurance code the physician members of the bureaus personally organized and financed an insurance company, which places the Washington State Medical Bureau and its component county bureaus under the supervision of the state insurance department, which in turn certifies as to the financial stability through adequate reserves deposited with it. The sole purpose of the insurance company is to legalize and guarantee the fulfilment of the medical service contracts issued by the bureaus.

Many unions, realizing the benefits to their members, have contracts covering their membership. The relationship between the unions and the medical service bureaus is one of real cooperation to the mutual benefit of the bureaus and the recipients of the service. The assistance rendered by the committees of the unions has been of great value in determining policy and coverage.

Last year the bureaus provided hospital coverage for the family, but it was realized that this was only partially solving the problem. The family of the wage earner should also be provided with professional care if he is to have medical economic security.

With the approval and endorsement of their many thousands of subscribers, the bureaus are now writing a family coverage that not only provides hospitalization for all medical and surgical cases but also pays for the doctor's services in all accident cases, major and minor operations, fractures, dislocations and other surgical procedures. This leaves the subscriber to pay only for the occasional office or house calls, which do not constitute an economic problem. The wage earner really has medical economic security, and the doctors of the state of Washington have found a way to provide it on a voluntary basis free from government intervention or at the expense of the taxpayer.

In 1935, when the need of providing medical care to recipients under the general assistance program was recognized, the state department of social security appointed the medical service bureaus as administrators of the medical and dental program in their respective counties. In 1941, when legislation was enacted providing complete, adequate medical care to recipients of old

age assistance, the medical service bureaus were again appointed administrators for that program.

The doctors through their medical service bureau have demonstrated their ability to manage all programs pertaining to medical care and its allied service. What they have done in Washington can likewise be done elsewhere. So say the progressive physicians of Washington.

Liberalization of Michigan Medical Service

Increase of benefits to subscribers with no increase in rates has been announced by Michigan Medical Service. The additional benefits were made effective April 1 and were enabled by the unusually strong financial position of the Michigan plan. Nearly 800,000 subscribers are entitled to the new benefits.

Among the liberalizations are removal of the previous limit of $150 for surgical service provided under the schedule of benefits and performed at the same time or for the same purpose, elimination of the waiting period on other obstetric services and provision for emergency surgical services for doctors in hospital outpatient departments.

Michigan Medical Service is sponsored by the Michigan State Medical Society. Its companion organization, Michigan Hospital Service, also instituted an increase in benefits on April 1, but an increase in subscriber rates was necessary to provide for the hospital service increase.

Ohio Medical Indemnity, Inc., Organized

Additional steps toward the organization of a medical, surgical and obstetric expense insurance company were taken by the officials of the Ohio State Medical Association on May 23, when articles for the incorporation of a company, to be known as "Ohio Medical Indemnity, Inc.," were filed with the secretary of state.

Negotiations with the superintendent of insurance for approval of its policy, schedule of benefits and rates, preliminary to the issuance by the superintendent of a certificate of authority to operate in Ohio, will be opened as soon as the company receives its charter from the secretary of state.

According to Dr. L. H. Schriver, Cincinnati, president of the Ohio State Medical Association and one of the incorporators, the new company plans to work closely with the prepaid hospital service—the Blue Cross—organizations of Ohio, making use of the sales, promotion, clerical and certain administrative facilities of the Blue Cross plans.

Two Savings Banks Subscribe to United Medical Service

Two more savings banks have subscribed to the expanded plan of United Medical Service, Inc., for the payment of doctors' bills in addition to surgeons' and obstetricians' bills in hospitals, it was announced on May 31 by Frank Van Dyk, vice president. They are the New York Savings Bank, with 120 employees, and the South Brooklyn Savings Bank, with a personnel of 132. Both banks are paying the cost of this service and of hospitalization under the Associated Hospital Service of New York for employees and their families.

Illinois Insurance Committee Makes Study

Dr. Charles H. Phifer, chairman of the Illinois committee, reports that "this committee has been currently engaged in making a special study of all prepayment plans for medical, surgical and hospital care in the United States. The committee has interviewed representatives of industrial organizations, railroads, insurance carriers, agricultural organizations, charitable hospitals and institutions in the state of Illinois. It likewise interviewed the medical representatives of the neighboring states regarding prepayment plans for medical, surgical and hospital care that are operating in their states or are in the process of formation."

Indiana Subdivides Committee Duties

Dr. W. U. Kennedy of New Castle, chairman of the Committee on Prepayment of Medical and Surgical Care, has divided his committee into three subcommittees each studying separate phases of the insurance problem. These subcommittees are ready to make their reports to the parent committee, which in turn will report to the House of Delegates.

New York Group Health Plan Adds Visiting Nurse Service

Group Health Cooperative, 70 Wall Street, announced on June 1 that, through the cooperation of the Visiting Nurse Service of New York, the Visiting Nurse Association of Brooklyn and the Visiting Nurses Association of Staten Island, it will provide visiting nurse service for subscribers to its medical care insurance plan at no increase in premiums. This is the first time that visiting nurse service has been included in a voluntary health insurance plan.

Subscribers will be entitled to the amount of service their doctors consider necessary in any illness covered by the medical plan. The group health plan provides insurance against doctors' services for any surgical care rendered in the home or doctor's office. The plan also covers maternity care.

The visiting nursing agencies in New York City have welcomed the opportunity offered by Group Health Cooperative to demonstrate the value of nursing services in connection with voluntary prepaid medical plans.

Missouri Medical Service Plan Launched

Missouri Medical Service, the nonprofit medical service plan through which Missourians may voluntarily enroll to obtain medical and surgical care in hospitals, was launched Monday, March 12, according to Dr. Carl F. Vohs, St. Louis, president of the new medical plan and chairman of the Medical Economics Committee of the Missouri State Medical Association. The plan is sponsored by the state medical association and local county medical societies throughout Missouri, comprising 3,250 doctors.

Enrolment in the plan will be offered through Blue Cross of St. Louis. The two organizations are separate, but considerable economy will be effected through management of the medical and surgical care plan by the Blue Cross.

At the outset, enrolment in the plan will be open only to the 480,000 employees of firms in Missouri which are members of the Blue Cross. Those belonging to Blue Cross will now have available a complete program for care while in hospitals.

Dallas Service Plan Expands

The recent appointment of Mr. Millard J. Heath as full time executive director of the Dallas County Medical Plan marks the first step in a program of expansion. For about five years this prepaid plan, which is sponsored by the Dallas County Medical Society as a nonprofit medical care plan for low income groups, has been operating on a limited basis with three industrial groups. It is now believed that the time has come to make the service available to a much larger group, and a survey is being made of major industries to determine their interest and possibility of participation. Enrolment is being offered only to employed persons, but the extended services include a consideration of wives and other dependents as soon as practicable. Subscribers are being offered complete medical care in the home, office or hospital, including surgery, x-ray and laboratory work.

Medical Legislation

MEDICAL BILLS IN CONGRESS

Medical and Dental Corps

Senator Downey, California, has submitted S. Res. 134, proposing that the Senate Committee on Military Affairs or a subcommittee thereof be directed to make a complete investigation as to the relative needs of the armed forces and the civilian population for the services of medical personnel with a view to ascertaining (1) whether such personnel can be released from the armed forces for civilian service without impairment of the war effort, (2) the speed with which demobilization of medical personnel in the armed forces can be accomplished as the needs of the armed forces diminish and (3) whether further action is necessary to insure an adequate supply of trained medical personnel to meet the future needs of the armed forces and the civilian population.

A bill to remove the limitation on the right to command of officers of the Dental Corps of the Army which limits such

officers to command in that corps, S. 916, has passed the Senate and has been favorably reported by the House Committee on Military Affairs.

A bill has been favorably reported to the House, H. R. 2477, proposing that during the present war and for six months thereafter an enlisted man of the Army who is entitled to wear the Medical Badge shall be paid additional compensation at the rate of $10 a month.

Dental Health

The Pepper Subcommittee on Wartime Health and Education has scheduled hearings for June 26, 27 and 28 on S. 190, proposing the establishment of a National Institute of Dental Research, and on S. 1099, proposing assistance to states in developing and maintaining dental health programs.

Veterans Administration

A bill has been introduced in the House by Representative Voorhis, California, H. R. 3463, proposing the creation of a National Veterans' Hospital Board with the following duties: (*a*) to advise the Administrator of Veterans' Affairs on all matters pertaining to the hospital or outpatient care of veterans and concerning the appointment of a National Executive Director for all veterans' hospitals; (*b*) to conduct a complete survey of all veterans' hospitals and to recommend to the Administrator and the National Executive Director such changes in personnel, such hospital construction and such other action as may be necessary; (*c*) to consult with the Administrator and the Director on the appointment of chief medical officers for all veterans' hospital units in the United States; (*d*) to provide adequate arrangements and facilities for continuous research on improved methods in the fields of medicine, psychiatry and all other types of care required by veterans; and (*e*) to prepare a schedule of proposed salaries, grades and classifications for all types of employees, professional or otherwise, in veterans' hospitals with a view to obtaining competent and qualified personnel.

A bill introduced by Representative Holifield, California, H. R. 3253, proposes to facilitate the receipt of hospital treatment and domiciliary care by former members of the armed forces at institutions nearest to their places of residence.

Three recent bills provide for the construction of new veterans' hospitals. One, H. R. 3428, introduced by Representative Latham, New York, contemplates the construction of such a hospital in the borough of Queens, city of New York, and the other two, H. R. 3475 and H. R. 3476, both introduced, by request, by Representative Rankin, Mississippi, provide for the construction of veterans' hospitals in central and southeastern Alaska, respectively.

Scientific Research

A bill introduced by Representative May, Kentucky, H. R. 3440, proposes an appropriation not to exceed $8,000,000 for each fiscal year to enable the National Academy of Sciences, through a research board for national security consisting of representatives of the Army, of the Navy and civilians of outstanding accomplishments, to provide for scientific research and advancement determined by the board to be desirable in the interest of national security.

Food, Drug and Cosmetic Act

The bill providing for the certification of batches of drugs composed wholly or partly of any kind of penicillin or any derivative thereof, H. R. 3266, has been reported to the House by the Committee on Interstate and Foreign Commerce with the recommendation that it pass. The committee report on this bill, H. Report No. 702, contains a letter from the Council on Pharmacy and Chemistry of the Association in support of the bill.

Miscellaneous

Senator Thomas, Oklahoma, has introduced S. 1123, proposing an appropriation of $1,000,000,000 per year for each of three fiscal years to enable the Federal Works Administrator to make loans and grants to public agencies for the construction of public works projects, including schools, hospitals, nurses' homes, sewerage systems and garbage and refuse disposal facilities.

STATE LEGISLATION

Alabama

Bill Introduced.—H. 448 proposes to enact a separate practice act for vocational nurses and to create a board of six, to be composed ultimately of three physicians and three vocational nurses, to examine and register applicants desiring to designate themselves as vocational nurses.

California

Bill Introduced.—A. 2211 proposes to prohibit a hospital having available facilities from refusing to render emergency medical care to any person who has been injured in an accident and is in need of immediate care. If the individual receiving such services is indigent and unable to pay therefor, the reasonable costs of the services are to be paid by the county.

Connecticut

Bills Passed.—The following bills have passed the house and senate: S. 865 proposing that nothing in the medical practice act shall prevent any student in or graduate from any school or institution giving instruction in the healing arts, approved as provided in the act, from taking supplementary training with any regularly licensed and reputable practitioner or from serving as an intern in a hospital. The present law provides such an exemption for any student in or graduate from any legal and reputable professional school; and Sub. for S. 879 proposing that any resident who has served in the armed forces of the United States and whose moral and educational qualifications are approved by the board of chiropractic examiners shall be licensed to practice chiropractic without examination; and Sub for H. 1031 proposing to direct the legislative council to make a comprehensive inquiry into the methods of professional and vocational licensing in the state. H. 402 has passed the house, to amend what in effect is the basic science act, proposing to change some detail in connection with the appointment of members of the state board of healing arts. It is proposed that the governor appoint one member of that board before July 1 to serve for six years and that on May 1, 1947 and biennially thereafter the governor shall appoint, *with the advice and consent of the general assembly*, one member to serve for six years. It is proposed also to provide compensation of ten dollars a day for each day of service for members of the board.

Bill Introduced.—Sub. for S. 84, to amend the charter of the Connecticut State Medical Society, proposes that its house of delegates be composed of (1) its president, president-elect, treasurer and secretary, (2) delegates elected annually by the several county medical associations and (3) the members of its council.

Florida

Bill Enacted.—H. 883 became a law without the approval of the governor on June 11, authorizing the creation and operation of corporations to operate nonprofit medical and/or surgical and/or hospital service plans.

Bills Introduced.—S. 704 proposes to authorize the governing board of any governmental hospital to prescribe the qualifications and standards of the physicians who may use its facilities, which qualifications shall require at least two years of service as a hospital intern as a prerequisite to the right to perform surgery. S. 806 proposes to prohibit, except on the prescription of a licensed physician, the retail sale of any sulfonamide drug, penicillin drug or any preparation for the treatment, alleviation or cure of gonorrhea, syphilis or chancroid.

Illinois

Bills Introduced.—H. 719 proposes to enact a practice act for professional chemistry and to authorize the department of registration to appoint an examining committee of nine professional chemists. A person practices professional chemistry within the meaning of the bill "who applies the principles and data of chemistry in any of its branches or phases in determining, governing or regulating the welfare of individual or of industry, or in the exposition of such principles in any oral or written report or in any procedure." H. 749 proposes to enact a bill to regulate the practice of professional bacteriology and to authorize the department of registration to appoint a committee of nine professional bacteriologists to examine applicants

cants for licenses to practice that profession. A person practices professional bacteriology within the meaning of the bill "who makes laboratory examinations in connection with the diagnosis of bacterial or viral diseases of man or animals, who prepares vaccines and antisera, who tests water, milk and other foods for evidence of contamination or the presence of disease producing micro-organisms, who tests surgical sutures and bandages, vaccines, antisera and pharmaceutical drugs for contamination with micro-organisms, who tests antiseptics, disinfectants and other drugs for their killing properties of micro-organisms, who prepares or tests cultures of nitrogen fixing bacteria, who prepares or tests antibiotics, who prepares organic substances by the action of micro-organisms and who assays vitamins, amino acids or other substances by microbiological methods."

Massachusetts

Bills Introduced.—H. 2029 proposes to prohibit the operation of a hospital, sanatorium or convalescent or nursing home without a license from the department of public health. H. 1980 proposes to make Middlesex University School of Medicine an approved medical school until July 1, 1949 and, in effect, to permit its graduates to be examined for licenses to practice medicine.

Ohio

Bill Introduced.—Sub. for H. 62 proposes that the practice of Christian science by a member in good standing of the Christian Science Church shall be lawful.

Official Notes

DOCTORS LOOK AHEAD

Remaining programs in the series of network broadcasts by the NBC and the American Medical Association will be on the air June 23 and 30 except in Chicago.

Doctors Look Ahead is broadcast each Saturday at 4:30 p. m. Eastern War Time (3:30 p. m. Central War Time, 2:30 p. m. Mountain War Time and 1:30 p. m. Pacific War Time) except in Chicago, where each week's program as broadcast on the network will be heard on the next Saturday afternoon at 3 p. m. Central War Time.

June 30. Health in Schools: A program devoted to health education and related topics in our schools, where doctors look ahead to greater progress in the next decade. Speaker Dr. Charles C. Wilson, Teachers College, Columbia University, speaking from New York.

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

At its meeting on Sunday, June 10, the Council on Medical Education and Hospitals of the American Medical Association voted to place on probation the Hahnemann Medical College of Philadelphia. This action was based on a detailed survey of the school carried out by the Secretary of the Council and the Secretary of the Association of American Medical Colleges April 3-6, 1945.

A medical school is placed on probation when significant but correctable deficiencies are judged to exist in the educational program. Such an institution remains on the list of approved schools maintained by the Council, with its probationary status indicated by a footnote. Hospitals approved by the Council may appoint graduates of such a school as interns, residents or fellows, and all otherwise qualified students entering or attending a school on probation are considered acceptable to the Council. In fact, so far as the students in residence are concerned, even if a school should be removed from the list of approved schools such action by the Council would become effective only after all students in the school at the time of the announcement of the action have had time to graduate.

The Council will give every assistance to this school in its efforts to improve the educational program sufficiently to warrant removal of the probation.

VICTOR JOHNSON, M.D., Secretary.

Bureau of Information

SUMMARY SHEETS FROM MINNESOTA AND WEST VIRGINIA

Completed county summary sheets have been received from the Minnesota State Medical Association through Mr. R. R. Rosell, executive secretary, and from the West Virginia State Medical Association through Mr. Charles Lively, executive secretary.

The accompanying table gives data from counties in each of these states. The column giving the number of persons per telephone is used as one index of the economic status of the area. Many physicians over 65 years of age are carrying on large practices and are doing much to maintain the health of communities. They are not included in computing physician population ratio, however, as the future needs of the communities will be largely dependent on younger physicians.

Minnesota

County [1]	Principal Cities [2]	Population	Physicians Under 65	Persons per Physician	Persons per Telephone [3]
Aitkin		12,856	3	4,285	8
Anoka		23,771			
	Anoka	6,426	6	3,962	17
	Columbia Heights	6,035			
Clay		22,733	9	2,526	9
	Moorhead	9,491			
Dodge		11,173	4	2,793	8
Hubbard		8,783	2	4,392	10
	Park Rapids	2,643			
Lac-qui Park		13,472	5	2,694	9
Lake of the Woods		3,994	1	3,994	10
Mille Lacs		13,212	4	3,303	6
Roseau		12,820	4	3,205	9
Yellow Medicine		15,302	9	1,700	8

West Virginia

County [1]	Principal Cities [2]	Population	Physicians Under 65	Persons per Physician	Persons per Telephone [3]
Barbour		16,457	8	2,057	41
Calhoun		8,839	1	8,839	10
Fayette		71,635	27	2,653	32
	Oak Hill	3,213			
	Montgomery	3,231			
Grant		7,424	3	2,475	81
Jackson		13,948	3	4,649	9
Lincoln		18,487	4	4,622	212
Mason		20,630	5	4,126	28
	Point Pleasant	3,538			
Mineral		19,779	9	2,198	17
	Keyser	6,177			
	Piedmont	2,677			
Wirt		4,935	1	4,935	17
Wyoming		29,700	9	3,300	92
	Mullens	3,026			

1. Bureau of Census, estimated population 1943.
2. Bureau of Census, population 1940.
3. Based on 1940 figures, American Telephone & Telegraph Company.

A current knowledge of needs of communities for doctors is essential if adequate help is to be given veteran medical officers in their problems of medical practice. These needs can be indicated on the summary sheets under "Remarks" by the state and county secretaries and are then available to inquiring medical officers. Frequent reports from state and county medical societies about needs of communities for doctors will help maintain current files and will increase the service of the Bureau.

With the information available on a completely filled out summary sheet, it is readily possible for an interested medical officer to make an initial selection of areas in which he might like to practice. Since vacancies are held open in many communities for doctors now in military service, further investigation by direct correspondence with state and county medical societies will always be necessary to insure an accurate report of the needs of individual communities.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Compulsory Hospitalization Bill Killed.—The compulsory hospitalization bill, assembly bill 2201, actively supported by Governor Warren, the C. I. O., the A. F. of L., the Parent-Teachers Association and the League of Women Voters, was killed in the assembly June 5. By a vote of 45 to 32 the assembly refused to override the recommendation of its public health committee and withdraw the bill from that committee. The opposition to the bill was presented by Howard Burrell, chief counsel for the Association of California Hospitals, who declared that the measure would "sovietize" the hospitals of California. Dr. Chester L. Cooley, San Francisco, presented the opposition of the California Medical Association and pointed out that the bill was similar to the original compulsory health insurance bills which had been killed by the assembly. Opposition of business groups was presented by Charles Bayer of the Los Angeles Chamber of Commerce and Pat Merrick of the California State Chamber of Commerce.

Activities of Hastings Foundation.—The Charles Cook Hastings Home for the study and treatment of tuberculosis, located north of Pasadena, is expected to open about August 1. Dr. Edward Kupka is medical director of the Hastings Foundation for Tuberculosis Research, Pasadena, set up by the will of Charles H. Hastings, and of the Charles Cook Hastings Home (THE JOURNAL, Dec. 30, 1944, p. 1158). *Science* reports that agreement has been made with the Veterans Administration Facility, San Fernando, to treat 20 veterans of the war who have developed tuberculosis, the entire cost of care to be paid by the Hastings Foundation. Dr. Horace R. Getz, research associate of the Henry Phipps Institute, Philadelphia, is director of the laboratories and will continue research on nutrition heretofore carried on by him in Philadelphia, which will include an attempt to learn the effect of nutrition on the course of tuberculosis. *Science* further reports that objective nutrition tests on the blood and biomicroscopy of the eyes, tongue and gums will be a part of the routine examination of the subjects, all of whom will receive a good standard sanatorium diet with one half being given food supplements. Progress of the disease in the two groups will then be carefully compared.

DISTRICT OF COLUMBIA

Dr. Owen Returns to North Carolina.—Dr. John F. Owen, who on May 1 became director of the new bureau of mental hygiene in the health department of the District of Columbia, has resigned to return to his position as superintendent of the State Hospital, Raleigh, N. C., according to the Washington *Times-Herald,* June 5. Dr. Owen's appointment to the new position was reported in THE JOURNAL, May 19, page 216.

Surveyor Board Named for Hospital Study.—A board of surveyors consisting of Charles E. A. Winslow, Dr.P.H., Col. Ira V. Hiscock, S.C., New Haven, and Dr. Claude W. Munger, New York, was recently named and charged to direct the health and hospital survey sponsored by the Washington Metropolitan Health Council, a division of the Council of Social Agencies, for the Washington Metropolitan area. The survey is expected to be completed within four months starting September 1 and will involve a study of facilities and activities of health agencies, hospitals and clinics, both public and private, in the metropolitan area lying in the District of Columbia, Prince Georges County, Montgomery County, Arlington County, Fairfax County and Alexandria City. The survey has the endorsement of the Community War Fund, the Washington Board of Trade, the Medical Society of the District of Columbia the six health officers of the area and the state commissioners of health of Maryland and Virginia. The Washington Metropolitan Health Council was recently created under the sponsorship of the Council of Social Agencies (THE JOURNAL, January 20, p. 173). Vice Admiral Ross T. McIntire, Surgeon General of the Navy, is chairman of the survey committee and Dr. Herbert P. Ramsey is head of the health division of the Council of Social Agencies.

ILLINOIS

Personal.—Dr. Charles E. Riseling was given a dinner May 2 in honor of his fifty-two years' service to Murphysboro and of forty-eight years' service as a member of the staff of St. Andrew's Hospital, of which he became one of the original members when it was founded in 1897.——Dr. George W. Ross was installed as mayor of Watseka on May 14.

Chicago

Medical Group Practice Council Holds Meeting.—A meeting of the Western section of the Medical Group Practice Council was held at the Palmer House, Chicago, June 6-7, with Dr. Samuel Bradbury, Philadelphia, as chairman. At the luncheon meeting on June 7 Dr. Kingsley Roberts of the Medical Administration Service, New York, presided. Drs. Morris Fishbein and Victor Johnson of the American Medical Association were guests, and Clarence Rufus Rorem, Ph.D., director of the Hospital Plan Commission of the American Hospital Association, also attended. This council is organized under the auspices of the Medical Administration Service, Inc., to promote the extension and improvement of medical group practice by preparing and disseminating publications regarding the standards, procedures, problems and values of this method of distributing medical care.

MARYLAND

Council on Medical Care Created.—A council on medical care has been created by authority vested in the state board of health by act of the 1945 session of the general assembly to provide consultation and advice in connection with the program to be administered by the newly established bureau of medical services (THE JOURNAL, May 12, p. 143). The following have been chosen members of the council to represent the organizations indicated:

Dr. Page C. Jett, Medical and Chirurgical Faculty of Maryland.
Dr. Earle Paul Knotts, Medical and Chirurgical Faculty of Maryland.
Dr. Jacob W. Bird, state board of health.
A. G. DuMez, Maryland Pharmaceutical Association.
Dr. James Douglass Shepperd, Maryland Medical Association.
F. Noel Smith, Maryland State Dental Association.
P. J. McMillin, Maryland District of Columbia Hospital Association.
Dorothy F. McBride, Maryland State Nurses Association.
Dr. Alan M. Chesney, Johns Hopkins University School of Medicine.
Dr. George Carroll Lockard, University of Maryland School of Medicine and College of Physicians and Surgeons.
Dr. Robert H. Riley, director of the state department of health.
Dr. George H. Preston, state commissioner of mental hygiene.
Dr. Victor F. Cullen, superintendent of Maryland state tuberculosis sanatoriums.
J. Milton Patterson, director of the state department of welfare.

Dr. Dean W. Roberts, chief of the bureau of child hygiene of the state department of health, was appointed chief of the bureau of medical services, which will administer a program furnishing medical care for indigent and medically indigent persons and will conduct and operate the chronic disease hospitals to be constructed in the postwar period.

MINNESOTA

Changes in Health Officers.—Dr. Rolv S. Hegge, Austin, has been named health officer of Mower County to succeed Dr. James J. Morrow, Austin.——Dr. Roland F. Mueller, Two Harbors, has been appointed health officer of Lake County.

Health and Medicine in War and Peace.—On June 5 Vice Admiral Ross T. McIntire, Surgeon General of the U. S. Navy, and James L. Morrill, LL.D., president-elect of the University of Minnesota, discussed "Health and Medicine in War and Peace" at a dinner meeting held under the sponsorship of the committee of founders of the Mayo Memorial.

The Johnston Lecture on Neurology.—Dr. Olof Larsell, professor of anatomy, University of Oregon Medical School, Portland, gave the first J. B. Johnston Lecture on neurology, May 11, at the University of Minnesota Medical School, Minneapolis. His subject was "Comparative Neurology and Our Present Knowledge of the Cerebellum." The lecture was endowed by Mrs. Johnston in memory of her husband, John B. Johnston, Ph.D., who served as professor of comparative neurology in the medical school from 1908 to 1915 and dean of the College of Science, Literature and the Arts from 1914 to 1937 (THE JOURNAL, February 3, p. 287).

NEW HAMPSHIRE

State Medical Election.—Dr. Richard W. Robinson, Laconia, was named president of the New Hampshire Medical Society at its annual meeting in Manchester, May 15. Other officers include Drs. Ralph W. Tuttle, Wolfeboro, vice president and Carleton R. Metcalf, Concord, secretary-treasurer.

NEW JERSEY

Ill Award Goes to Dr. Sprague.—The Edward J. Ill Award of the Academy of Medicine of Northern New Jersey was presented to Dr. Edward Wharton Sprague, Newark, during the annual meeting of the academy, May 17, "in recognition of his attainments as a surgeon and his contribution to the public welfare through his service in many civic and social welfare organizations." Dr. Harrison S. Martland, Newark, professor of forensic medicine, New York University College of Medicine, gave the principal address, on "Oh Why Should the Spirit of Mortal Be Proud?"

NEW YORK

Prevalence of Spotted Fever.—In 1944 17 cases of Rocky Mountain spotted fever, 4 of which terminated fatally, were reported in the state, exclusive of New York City, more than in any previous year on record. Although the disease was first recognized in this state in 1912, it has been only in the past decade and particularly in the last six years that a noticeable increase in incidence has been observed. This fact, coupled with the occurrence of sixteen deaths among the total of 86 cases reported from the area, plus what appears to be a gradual extension of the infection from the initial focus discovered in 1912, gives the health authorities in the state some cause for concern, according to *Health News*. Except for a single infection acquired accidentally in a Rockland County laboratory experimenting with the disease, all the cases on record in the New York State Department of Health have been confined to the Long Island area. Since the first 3 cases on record in the state were reported in Gardiner's Island, 2 with onset in 1912 and 1 in 1913, no cases were recognized until 1924, when 1 case was reported at the eastern end of Long Island proper in Suffolk County. Subsequent cases were confined to this county until 1939, when the first infections contracted in Nassau County were reported. In the group of 17 cases in 1944 the ages ranged from 3 to 72 years, about equally divided as to sex. Onsets of illness were confined to the period May through September, 6 in May, 3 in June, 3 in July, 4 in August and 1 in September. In 7 there was a definite history of tick bite and in 6 others evidence of contact with a tick. It is significant that in 8 cases the disease apparently was acquired through contact with tick-infested domestic animals: dogs in 7 cases and a cat in 1 case.

New York City

Marvin Thompson Resigns at Warner Institute.—Marvin R. Thompson, Ph.D., has resigned as president and director of the Warner Institute of Therapeutic Research, effective July 1.

Kellogg Grant to Train Hospital Executives.—The W. K. Kellogg Foundation, Battle Creek, Mich., has given Columbia University a grant of $60,000 to establish a course of training for hospital administrators, the New York *Times* reported June 5. The work will be carried out in the DeLamar Institute of Public Health and will be available for graduate students. The *Times* stated that plans already had been made for the Columbia faculty of medicine to carry out the training program in cooperation with hospitals and other organizations throughout the country.

OHIO

Industrial Commission Adopts Revised Medical and Surgical Fee Schedule.—The Ohio Industrial Commission has adopted a revised medical and surgical fee schedule, effective May 1, after a series of conferences with the committee on workmen's compensation of the Ohio State Medical Association and a similar committee of the Ohio State Dental Society. A new rule on physical therapy was inserted stating that fees for physical therapy will not be approved for more than ten treatments unless authorized. Under the old rule, fees for such treatment were not allowed unless the treatment was authorized in advance by the commission. The period of after-care covered by a flat fee in surgical procedures, dislocations, fractures, amputations and ophthalmologic procedures was reduced from ninety days to sixty days. This means that additional fees may be paid for services in extended cases—services required after sixty days. A period of three weeks was established as the period covered by the flat fee in ear, nose and throat surgical procedures. The fee for treatment at office after the first treatment was increased from $1.50 to $2, and the fee for treatment at the hospital after the first treatment was increased from $2 to $2.50. Fees were increased in eleven surgical procedures, in six items involving dislocations, in seventeen procedures involving fractures, in five types of amputations, for five ophthalmologic procedures, for two ear, nose and throat procedures and for three x-ray items. The fee for administration of anesthesia in prolonged operations was increased. Under the new schedule the anesthetist is allowed a fee of $10 for the first thirty minutes or fraction thereof and an additional $5 for each succeeding thirty minutes or fraction thereof. The old fee was $10 regardless of the time consumed by the operation. A new item was inserted in the schedule providing a fee of $3 for affidavits furnished by the physician on request of the commission and containing information used as a basis for adjudication of the claim. An entirely new section was inserted in the schedule entitled "Reconstructive Surgery." Such cases (mostly difficult orthopedic and reconstructive surgical cases) must have the authorization of the commission. The schedule provides for six months' after-care under a flat fee which includes the cost of the first cast.

PENNSYLVANIA

District Meeting.—The Tenth and Eleventh Councilor Districts medical societies held their annual meeting at the Penn-Albert Hotel, Greensburg, June 21. Among the speakers were:

Dr. George W. Ramsey, Washington, Facts Regarding the Rh Factor.
Dr. Howard G. Schleiter, Pittsburgh, Identification of Certain Forms of Heart Disease.
Dr. William Bates, Philadelphia, Segmental Pain Suggesting Visceral Disease.
William S. Livengood Jr., Harrisburg, Governmental Paternalism and Inefficiency.

A feature of the meeting was the presentation of testimonials to members who have completed fifty years of practice by Dr. William L. Estes Jr., Bethlehem, president-elect of the state medical society. Those honored included Drs. Albert H. Aber, Dravosburg; Francis J. Madden, Duquesne; Thomas G. Simonton, Pittsburgh; John D. Sin[illegible] liam J. K. Snyder, Avalon; Nathan [illegible] John M. Davis, Darlington; Milton L. [illegible] John B. Lowman, Johnstown; Bryant E. Sankey, New Castle; Kate W. Leatherman, Greensburg; Mary L. Montgomery-Marsh, Mount Pleasant, and Harry J. Stauffer, Jeannette.

Philadelphia

Personal.—James P. Lackey, Ph.D., has been named editor of the undergraduate subjects in the sciences for the Blakiston Company.

Fiftieth Anniversary of Laboratory.—On May 20 the laboratory of the Philadelphia Department of Health observed its fiftieth anniversary. Features included a broadcast over WPEN May 19 and an open house the following day.

Dr. Schaeffer Receives Strittmatter Award.—The 1944 Strittmatter award was presented to Dr. Jacob Parsons Schaeffer, professor of anatomy at Jefferson Medical College of Philadelphia, during a special meeting of the Philadelphia County Medical Society May 16 "in recognition of his long and distinguished career as a teacher, author and scientist in the field of anatomy and his sincere and untiring devotion and constructive efforts to safeguard high standards of medical research." This is the twenty-second presentation of the award, which consists of a gold medal and scroll and was made possible in 1923 through the generosity of Dr. Isidor P. Strittmatter. The DaCosta Oration was presented on this occasion by Col. James Barrett Brown, M. C., on "Plastic Surgery in the Military Service."

RHODE ISLAND

Pawtucket Society Observes Fiftieth Anniversary.—On June 6 the Pawtucket Medical Association observed its fiftieth anniversary with a day's celebration at the Pawtucket Golf Club.

Dr. Mowry Retires as Treasurer.—Dr. Jesse E. Mowry, Providence, has retired as treasurer of the Rhode Island Medical Society, concluding twenty-two years' service in the position. Dr. Mowry was president of the Providence Medical Association in 1903, delegate to the American Medical Association in 1916-1917 and president of the Rhode Island Medical Society in 1920.

State Medical Election.—New officers of the Rhode Island Medical Society include Drs. Herman C. Pitts, Providence, president-elect; John F. Kenney, Pawtucket, president; Joseph H. Ladd, La Fayette, vice president; Charles J. Ashworth, Providence, treasurer; Alfred L. Potter, Providence, assistant secretary, and George Raymond Fox, Pawtucket, assistant treasurer. Dr. William P. Buffum, Providence, is secretary.

Surgical Plan Committee Named.—The state medical journal announces a new eleven member committee of physicians and laymen who will study voluntary programs to provide for prepaid medical and surgical insurance similar in operation to the Blue Cross Plan. Lay members of the new committee elected by the six physicians previously chosen by the house of delegates of the state medical society include:

Roderick Pirnie, Providence, insurance executive and state director of the War Finance Committee.

George C. Davis, Providence, lawyer and a member of the board of directors of the Blue Cross.

Charles H. Baker, Providence, head of the industrial firm of Charles H. Baker, Inc.

Ralph Kenyon, Pawtucket, president of the Pawtucket Institution for Savings and a member of the board of trustees of Memorial Hospital.

Harold L. Amrhein, Woonsocket, vice president of the American Paper Tube Company and a trustee of Woonsocket Hospital.

The physicians are Drs. Samuel Adelson, Newport; Hartford P. Gongaware, Westerly; Leo V. Conlon, Woonsocket; George Raymond Fox, Pawtucket, and Herman C. Pitts and Arthur E. Martin, Providence. Dr. Pitts is chairman of the new committee and John E. Farrell, executive secretary of the state medical society, is secretary. Present plans call for a complete review of distribution of medical and surgical services in Rhode Island and also a study of existing medical service plans in other parts of the country that might be adaptable to Rhode Island. The state journal, in its announcement, stated that in the final day of the legislative session the general assembly passed in concurrence an act providing for the incorporation of nonprofit medical service corporations and defining their powers.

TENNESSEE

Waller Leathers Retires.—Dr. Ernest W. Goodpasture, since 1924 professor of pathology, and also associate dean, Vanderbilt University School of Medicine, Nashville, has been appointed dean to succeed Dr. Waller S. Leathers, who will retire June 30. Dr. Sam L. Clark, professor of anatomy at the medical school, has been named associate dean, and Dr. William W. Frye, associate professor of preventive medicine and public health, has been designated professor and head of the department of preventive medicine and public health. The announcement concerning these changes was made during a meeting of the university's board of trust. Dr. Goodpasture received his A.B. in 1907 at Vanderbilt University and graduated at Johns Hopkins University School of Medicine, Baltimore, in 1912. He has been associated with the school since 1924, following years of service at institutions that included Johns Hopkins, Harvard and the University of the Philippines. Dr. Leathers, who graduated at the University of Virginia Department of Medicine, Charlottesville, Va., in 1895, has been dean of Vanderbilt school of medicine and head of the department of preventive medicine and public health since 1928.

UTAH

Personal.—Dr. David C. Budge, medical director of the William Budge Memorial Hospital, Logan, since it was organized in December 1914, has resigned. Dr. Scott M. Budge, associate medical director, was named to succeed him. The latter has been succeeded as associate medical director by Dr. Oliver Wendell Budge.——Dr. Clay B. Freudenberger, professor and head of the department of anatomy, University of Utah School of Medicine, Salt Lake City, is spending the spring quarter as visiting professor of anatomy at the Louisiana State University School of Medicine, New Orleans.

VERMONT

The Osler Lectures.—Dr. Wesley Bourne, lecturer in pharmacology, McGill University Faculty of Medicine, Montreal, will deliver the Osler Lectures at the University of Vermont College of Medicine at the Fleming Museum, Burlington, July 5-7. His subject for the three lectures will be "Anesthesia: Some Contemplations."

WASHINGTON

New Building for Blood Bank.—Plans will soon be completed for construction of a $100,000 one story reinforced concrete building in Seattle to house the central blood bank (THE JOURNAL, Aug. 5, 1944, p. 982). The project will be financed by contributions, which already total $150,000, to cover construction, equipment and maintenance for a limited period. The blood bank was established a year ago by contributions from twenty business men under the inspiration of Mr. Emil G. Sick, according to *Northwest Medicine*. The land for the blood bank was donated by Dr. Simon Maimon Samuels, Seattle.

Portrait of Physicians.—A portrait of Drs. Walter C. Woodward and Homer D. Dudley, Seattle, was unveiled at the Rainier Club during a dinner meeting of the Seattle Surgical Society and the Puget Sound Surgical Society, April 27. The portrait was presented by the Seattle Surgical Society to the King County Medical Society, May 7, and will be hung permanently with portraits of other physicians in the society's rooms at the Medical-Dental Building auditorium. For the past fifteen years the surgical group has presented an annual two day program, one half of which was serious. The other half is a "high jinks" consisting of a script written and directed by Dr. Woodward and Dr. Dudley and usually devoted to "take-offs" on characteristic traits of their fellow physicians, according to the Seattle *Times*. The portrait shows the two physicians in informal pose and is the work of Neale Ordayne, formerly of Seattle and now located in Texas.

WEST VIRGINIA

Advisory Committee for Legislative Interim Committee.—Governor Clarence W. Meadows has appointed eight physicians as members of an advisory committee which is being set up under the provisions of a concurrent resolution (H. C. R. 4) adopted by the legislature for the purpose of consulting with a legislative interim committee in an investigation and study of public health problems in West Virginia (THE JOURNAL, May 5, p. 44). Members of the advisory committee are Drs. Delivan A. MacGregor, Wheeling; Edwin A. Trinkle, Weston; George O. Martin, Martinsburg; Newman H. Dyer, Bartley; Robert J. Wilkinson and Ray M. Bobbitt, Huntington; Richard O. Rogers, Bluefield, and George F. Grisinger, Charleston.

GENERAL

National Farm Safety Week.—July 22-28 has been designated the National Farm Safety Week, according to Presidential proclamation.

Safety Council Seeks Editorial to Reduce July Fourth Accidents.—An award of $200 for a Fourth of July editorial to help cut down the Fourth of July accident toll is announced by the National Safety Council.

Twenty-Five Years of Hospital Progress.—The twenty-fifth anniversary of *Hospital Progress*, the official journal of the Catholic Hospital Association of the United States and Canada, was observed with its May issue.

Activity Group Therapy for Children.—A training institute in activity group therapy for children will be conducted in New York City under the direction of the American Group Therapy Association. Additional information may be obtained from the association, 228 East Nineteenth Street, New York 3.

Louis Dublin Returns to Metropolitan.—Louis I. Dublin, Ph.D., second vice president and statistician of the Metropolitan Life Insurance Company, has completed his assignment as full time assistant to Basil O'Connor, chairman of the American Red Cross, and as chairman of the organization's administrative committee and has resumed his activities with the insurance company. Dr. Dublin will continue to assist Mr. O'Connor in the long-term policies and plans of the Red Cross and will be active in relation to the operation of the New York City chapters.

Chemical Awards.—The American Chemical Society has awarded the $1,000 Eli Lilly & Company prize for research in biochemistry to Max A. Lauffer Jr., Ph.D., associate professor of physics at the University of Pittsburgh, and the $1,000 Borden Company prize for research in the chemistry of milk to Ben H. Nicolet, Ph.D., senior chemist of the bureau of dairy industry, U. S. Department of Agriculture, Beltsville, Md., the New York *Times* reported June 3. Dr. Lauffer, a former associate at the Rockefeller Institute for Medical Research, was cited for "significant contributions to the study of the physical chemistry of viruses, the kinetics of virus protein denaturation, and the size and shape of macromolecules." Dr. Nicolet was cited for fundamental chemical investigations in the chemistry of milk proteins.

Life Insurance Fund Proposed for Research.—Plans to establish a life insurance fund that would advance more than $500,000 each year for the promotion of medical research were disclosed May 31 by Mr. M. Albert Linton, Philadelphia, chairman of a joint committee of the American Life Convention, Chicago, and the Life Insurance Association of America, New York, according to the New York *Times*. The funds at first would be devoted to diseases of the heart and arteries, it was stated. Foundation grants in 1940 for research into this group of diseases amounted to only 17 cents per

death from these causes against $2.18 per death in cancer, the *Times* states. The life insurance medical research program is to support existing research rather than to establish new research centers. It proposes to extend grants to institutions equipped for research in the chosen field and support carefully selected men who had completed their medical studies and shown special ability in research. Most of these men are now in the armed forces and unless they are helped they may turn to other fields. The new project proposes to assign them as research associates with experienced men already working on cardiovascular diseases.

Science Talks Feature Symphony Intermission.—Edwin J. Cohn, Ph.D., professor of biochemistry, Harvard Medical School, Boston, on May 27 gave the first in a new series of science talks which now feature the intermission of the New York Philharmonic program sponsored by the U. S. Rubber Company. Dr. Cohn's subject was "Blood and Blood Derivatives." The theme of the series is "Science Looks Forward" and the talks in the current group include:

Philip R. White, Ph.D., associate in the department of animal and plant pathology, Rockefeller Institute, Princeton, N. J., Roots, Nerves and Kidneys, June 3.
Charles K. Leith, Sc.D., head of the metals and minerals branch, Production Research and Development, War Production Board, Madison, Wis., Metals in War and Peace, June 10.
Robert M. Yerkes, Sc.D., professor of psychobiology, Yale University School of Medicine, New Haven, Conn., Chimpanzees as Servants of Science, June 17.
Henry N. Russell, Ph.D., research professor of astronomy, Princeton University, Princeton, N. J., Are the Other Planets Habitable? June 24.
John G. Kirkwood, Ph.D., Ithaca, N. Y., associate editor of the *Journal of Chemistry and Physics*, What Is a Liquid? July 8.
Isaiah Bowman, LL.D., president, Johns Hopkins University, Baltimore, The New Geography, July 15.
Dr. George R. Minot, Boston City Hospital, Anemia, July 22.
George R. Harrison, Ph.D., professor of physics, Massachusetts Institute of Technology, Cambridge, Atoms, July 29.
Robert C. Murphy, Sc.D., zoology, ornithology, American Museum of Natural History, New York City, subject not announced, August 5.
George B. Cressey, Ph.D., geology, geography, Syracuse University, Syracuse, N. Y., Our Northern Neighbor, China, August 12.
Charles E. K. Mees, Sc.D., director of research and development of the Eastman Kodak Company, Rochester, N. Y., Cows, Movies and Color Photography, August 19.

The Lasker Awards for Fertility Research and Maternal Care.—The Planned Parenthood Federation of America announces two $500 Lasker Awards for significant contribution to the improvement of maternal health care and for research in human fertility. The awards will be given to the scientist making the most significant contribution in research in human fertility, either in the control of conception or in the correction of infertility and to the public health service in a state or community for meritorious action in developing a complete program of maternal health care, including child spacing. The individual recipient of the award will be the executive officer most responsible for the development of the program. The fertility award will be given in honor of the late Dr. Hannah M. Stone, first medical director of the Margaret Sanger Research Bureau. The public health award will be in honor of Mrs. Margaret Sanger, founder of the birth control movement and at present honorary chairman of the federation. The awards will be presented at the annual dinner of the Planned Parenthood Federation of America in New York in January 1946. Deadline for submission of entries for the awards will be December 1. Two similar awards were presented last January to John MacLeod, Ph.D., of the department of anatomy, Cornell University Medical College, New York, and to Dr. Felix J. Underwood, Jackson, Miss., executive officer of the Mississippi State Board of Health. Any individual wishing to qualify for the awards or to suggest the name of a scientist, physician or public health official who might do so should address the medical committee, Planned Parenthood Federation of America, 501 Madison Avenue, New York 22.

Special Committee to Study New Approach on Cancer.—A special committee on growth consisting of fourteen experts has been appointed at the request of the American Cancer Society and in cooperation with the division of medical sciences of the National Research Council to project an "unprecedented approach" to the cancer problem. Authorities from fields as scattered as plant biology and genetics agreed to consolidate their information and plans in one organization, which will in turn encourage research through widespread grants of merited fellowship. The approach differs from all others heretofore in that cancer sometimes has been regarded as a distinct field, a tendency which many experts regard as a fallacy. The new program will attempt to advance the basic knowledge about cancer as well as encourage the fuller usage of what is known already, although in this second respect considerable gains are being made. The committee on growth will seek "to support institutions and individuals whose research work is related to finding new methods of treating cancer." Other objectives will be:

To make grants of such magnitude that individual researchers will be able to appoint subordinates for long training periods.
To arrange for the economic long-range security of researchers interested in the field.
To arrange for conferences of competent groups to interchange reports.
To make surveys to analyze the problems and progress relating to cancer.
To initiate and plan broad or specific programs of research.

The committee on growth expects some of the later nominees for fellowships to be men currently in the armed services. Rather than make the selections itself, the National Research Council will designate certain institutions with whose activities it is familiar, to make the awards in turn. Just as the committee membership has not been limited to cancer specialists, the research council pointed out the fellowships would be available to a diversity of candiates, in even such fields as engineering. Funds for research will come from the $5,000,000 campaign which has been under way recently. Members of the executive committee include Dr. Cornelius P. Rhoads, medical director of Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York; Clarence C. Little, Sc.D., Roscoe B. Jackson Memorial Laboratory, Bar Harbor, Maine; Dr. James B. Murphy, Rockefeller Institute for Medical Research, New York, and Dr. Milton C. Winternitz, Yale University School of Medicine, New Haven, Conn. Others on the committee on growth are:

Dr. Alphonse R. Dochez, Columbia University College of Physicians and Surgeons, New York.
Dr. A. Baird Hastings, Harvard Medical School, Boston.
Dr. Charles B. Huggins, University of Chicago.
Donald F. Jones, Sc.D., Connecticut Agricultural Experiment Station, New Haven.
Carl R. Moore, Ph.D., University of Chicago.
Dr. John J. Morton Jr., University of Rochester School of Medicine and Dentistry, Rochester, N. Y.
Dr. Eugene P. Pendergrass, University of Pennsylvania School of Medicine, Philadelphia.
Dr. Florence R. Sabin, Denver.
Dr. Howard C. Taylor Jr., Bellevue Hospital, New York.
Merle A. Tuve, Ph.D., Johns Hopkins University, Baltimore.

FOREIGN

Albert Szent-Györgi in Moscow.—Dr. Albert Szent-Györgi, professor of medical chemistry, Szeged University, Szeged, Hungary, who won the Nobel Prize in 1937 for his work with vitamin C, is reported to have arrived safely in Moscow from Budapest, according to the New York *Times*. It was stated that the Swedish legation in Budapest managed to save Professor Szent-Györgi from the Nazis by employing him as a chauffeur.

Egypt Approves Birth Control.—The Grand Mufti of Egypt, highest judicial authority under Moslem religious law, has sanctioned the practice of contraception in marriage under a wide variety of circumstances ranging from ill health to economic hardship. The approval was contained in a "fatwa," or judgment, which also permits abortion prior to the "quickening of the embryo" in cases in which the life of the mother, the "prospective child" or a child already born may be threatened. The announcement of the sanction was released through the Planned Parenthood Federation of America, New York.

Death Rate Increases.—During the four week period starting March 1 the death rate in Amsterdam was three times as high as during the corresponding period in 1939, according to the Netherlands Information Bureau. The very young and the very old whose resistance had been lowered by years of undernourishment were the groups hardest hit. The report indicates that there has been considerable increase in communicable diseases. Diphtheria, which in prewar years showed a rate of 400 to 600 annually, assumed epidemic proportions during 1944, when 7,800 cases were reported in Amsterdam alone. From 20,000 to 30,000 persons were found to be suffering from hunger edema, while tens of thousands of others were at the brink of starvation, it was stated. Netherlands health authorities were startled by a report from the chief of Allied Supreme Headquarters public health branch that "health conditions in Holland were not as bad as expected." The statement at SHAEF by Major General Warren F. Draper, U. S. Public Health Service, declared that the special feeding teams that had been alerted for action "were not needed." In reply to this, Dutch health authorities who had just returned from an eye witness tour of the western provinces declared that even two weeks after liberation people were still dying of starvation, while many were too weak even to reach the new distribution centers. Far from being "not needed," the twenty-nine feeding teams operating in the western provinces have been increased to forty-three. Eight of these teams are operating in Amsterdam, four in The Hague, six in Rotterdam and the others in various towns where large numbers of starvation victims have been found.

Foreign Letters

LONDON

May 19, 1945.

The British Council of Rehabilitation

As shown in previous letters to THE JOURNAL, war injuries have led to the concentration of attention on the problem of rehabilitation. A British Council of Rehabilitation has been established (1) to act as a coordinating center for the various interests concerned in the widest aspects of rehabilitation, (2) to promote and correlate courses of study, (3) to invite the active cooperation of government departments, hospitals, universities, training colleges, educational institutions and research foundations in promoting the study and practice of rehabilitation, (4) to secure the active cooperation and participation of commerce, industry and professional bodies in the problems of resettlement, (5) to encourage the formation of follow-up schemes for the rehabilitated and (6) to consider, promote or oppose legislation which may affect the interests of the disabled and to make such representations as may be desirable. The council will comprise two representatives from each of its member organizations, elected members and such others as the council may from time to time appoint. The member organizations are the Association of Industrial Medical Officers, the Association of Occupational Therapists, the Board of Registration of Medical Auxiliaries, the British Federation of Social Workers, the British Hospitals Association, the British Legion, the British Medical Association, the British Orthopedic Association, the Central Bureau for Insurance Nursing, the Central Council for the Care of Cripples, the Chartered Society of Physiotherapy, the Industrial Orthopedic Society, the Institute of Labor Management, the Miners Welfare Commission, the National Association for the Prevention of Tuberculosis, the National Institute for the Blind, the National Institute for the Deaf, the National Institute of Industrial Psychology and the Research Board for the Correlation of Medical Science and Physical Education.

Accidents from Gas Cylinders Used with Anesthetic Apparatus

The serious risk that the pipe line used with anesthetic apparatus may in error be connected with the wrong cylinder, e. g. to a cylinder containing nitrous oxide instead of oxygen, has led the Ministry of Health to send a circular to hospitals. A number of fatal accidents have occurred. The minister of health is advised that where it is the practice for any person other than the anesthetist to replace gas cylinders on anesthetic apparatus or to connect such apparatus to a pipe line installation, the risk of accidents would be minimized if arrangements were made for a second person, preferably a doctor, to examine the connections to ensure that a mistake has not been made. It is suggested that the person responsible for the examination might on each occasion also be required to make a note of the fact by signing a record book especially kept for the purpose.

The Treatment of Starvation Under the Germans

The treatment of cases of advanced starvation in German concentration camps and in occupied countries robbed of their food supplies, especially the Netherlands, is a grave problem. Impressed with the evidence of the value of hydrolysates for alimentation by the intravenous or oral route, the military authorities are providing this treatment. They are also testing the efficacy of plasma and serum, which have been supplied from the Lister Institute in large quantities. Glucose is also given in large quantities to spare the amino acids for purposes of repair, and vitamins. The results are not yet available.

A less serious problem was that of Dutch children, aged 7 to 15 years, brought to England from the Netherlands. They had been living for a long time on bread, potatoes and cabbage. They did not appear much wasted but were undersized. The extent to which they were underweight is shown by the fact that they gained up to 6 pounds 6 ounces (2,900 Gm.) in three weeks on a proper diet. But in the starvation areas of the Netherlands there are children whose diet has fallen to 300 calories a day and who will present a more serious problem.

English Books to Be Translated and Produced for Russia

An agreement has been signed at the Soviet embassy in London between Mezhdunarodnaya Kniga of Moscow and Hutchinson, the English publisher, by which the former will distribute Russian translations of English books. These books will be translated and produced in England by the English publisher and exported to Russia. The agreement will hold for a minimum period of three years. The books to be translated have not yet been announced, but no doubt medical books will figure largely among them. This is further evidence of the looking of the European nations to London for a lead after the war and the desire that the British capital should succeed to the hegemony formerly held by Berlin, which were mentioned in previous letters to THE JOURNAL.

BRAZIL

(From Our Regular Correspondent)

RIO DE JANEIRO, May 2, 1945.

The Sanitation Projects of the Amazon and the Rio Doce

Dr. George C. Dunham, director of the medical division of the Bureau of the Coordinator of Inter-American Affairs, recently spent a few days in Brazil to inspect the work of some of the projects of the Special Service of Public Health (the SESP, as it is called in Brazil), a medical organization run in cooperation by the governments of the United States and Brazil. Dr. Paulo Antunes is the director of the Amazon project, with headquarters at Belem, state of Pará, and Dr. Ernani Braga is the director of the Rio Doce project, with headquarters at Vitoria, state of Espirito Santo. Dr. H. V. Markham, director of the Central Hospital at Belem, and two more doctors are the only Americans at present connected with the two projects, the rest of about 3,000 officials and workers being Brazilians. Almost 50 Brazilian physicians are now studying in the United States, through fellowships awarded by the Institute of Inter-American Affairs, to work, after their return, in the two projects. The Schools of Nursing of São Paulo and Belem are training more than 50 young women to be used as nurses in the same work. In the vast region of the Amazon basin, where rivers are almost the only means of communication, many scattered treatment stations have been established for the campaign against malaria. Small steamers and launches are used to transport doctors, nurses and other workers, some of these small vessels being employed as mobile clinics. Several district laboratories have been established, where simple entomologic work is performed in coordination with the central laboratory at Belem, Pará. The International Health Division of the Rockefeller Foundation transferred to the SESP its specialized personnel who had been previously used in the campaign to eradicate the anopheline Gambiae imported from Africa, as well as an important bulk of equipment suitable to this kind of work. Since August 1942 the Institute Evandro Chagas of Belem, a branch of the Oswaldo Cruz Institute of Rio de Janeiro, has been closely cooperating in the Amazon project, with a modern hospital, a great laboratory and a training school. There are other hospitals at Manaos, Breves and Santarem, which are the principal cities of this section of the country.

Treatment of Pulmonary Tuberculosis with Thoracoplasty

Dr. Eduardo Etzel of the Vicentina Aranha Sanatorium at São José dos Campos, state of São Paulo, has just published a report on 122 consecutive cases of pulmonary tuberculosis treated with thoracoplasty. In 22 cases the treatment was not completed. Dr. Etzel points out the futility of attempting the thoracoplasty in patients whose pulmonary condition does not permit a good surgical collapse. Of the 100 cases in which the treatment was completed, there were unilateral lesions in 65 and bilateral lesions in 35. In the first group, 57 cases were cured, or 87.6 per cent. Etzel believes that the minimum period of six months is absolutely necessary to appraise the good results of thoracoplasty. The poor results in the 8 unilateral cases were caused by late hematogenic dissemination (1), by contralateral postoperative dissemination (1), by tracheobronchial tuberculosis (2), by residual tuberculous process (2), by residual cavity (1) and by secondary open cavity (1). In the group of bilateral cases 19, or 54.2 per cent, were cured. The poor results in the 16 bilateral cases were caused by contralateral cavity (7), noncavitary extensive fibrous lesions (3), contralateral pneumothorax with cavity (2), contralateral pneumothorax and residual cavity (2), contralateral pneumothorax with exudative lesions (1) and contralateral exudative lesions (1). A careful selection of cases must be made to determine the efficiency of the respiratory function, to avoid the operation on patients who may later present chronic dyspnea, causing permanent infirmity and even death. The stability of the lesion that has to be collapsed and the degree of fibrosis or the degree of productive reaction must be taken into consideration, as thoracoplasty is contraindicated in cases in which there are progressive and "soft" lesions without fibrous reaction. In cases with bilateral involvement the thoracoplasty must be performed only if the contralateral lesions are regressive, arrested or controlled through pneumothorax. Tracheobronchial tuberculosis is a contraindication to thoracoplasty if the disease is advanced or bilateral. In case of fibrous stenosis of a main bronchus, dilation is necessary before the thoracoplasty. In cases of tracheobronchial tuberculosis treatment of the pulmonary lesion must be performed first.

Brief Items

Dr. Pasteur Valéry-Radot of Paris, head of the French cultural mission to South America, is now in Rio de Janeiro. At the Medical School of the university he delivered a lecture on "French Medicine During the War."

Dr. George K. Strode, director of the International Health Division of the Rockefeller Foundation, spent a number of days at Rio de Janeiro, where he was invited to attend a special meeting held by the Brazilian Society of Hygiene in his honor and a luncheon, during which he was greeted by Dr. Afranio Peixoto, professor emeritus of hygiene at the Rio de Janeiro University. Dr. Strode was the head of the staff of the International Health Division in Brazil from 1921 to 1926.

A model health center has been inaugurated at Petropolis, the summer capital of Brazil (population 40,000). The building has been erected by the federal government and equipped by the state of Rio de Janeiro to be used as a training center for health officers and for public health nurses as well as a special demonstration of modern public health administration. The director of the center, Dr. Oswaldo L. Da Costa, has a diploma in public health from the Johns Hopkins University.

Dr. Francisco Gugliotti has been appointed director of the Hospital São Sebastião of Rio de Janeiro, the institution in which the acute cases of transmissible diseases are isolated.

The Legião Brasileira de Assistencia is now building a hospital for tuberculous children at Fortaleza, state of Ceará.

Dr. Antonio Murtinho Nobre, a practitioner of medicine in the city of São Paulo, died at Rio de Janeiro, aged 66.

MEXICO

(From Our Regular Correspondent)

MEXICO CITY, May 25, 1945.

United States Physicians Excluded

United States physicians are virtually excluded from practicing in Mexico under the terms of a new and rigid federal law designed to eliminate foreign influences from the Mexican scientific professions. The legislation, which was announced on May 26 by publication in the *Official Daily*, a government organ, took effect two days later. Although it lays down a complete system of control for a number of professions, the most important section of the law, as far as doctors of the United States are concerned, is that declaring "no foreigner can practice, in the Federal District and territories, the scientific professions covered by this law." The medical profession is specifically named as one of the fields which have been closed to foreigners. Nevertheless, government sources indicated that physicians already practicing here will probably not be affected. While this point has not as yet been clarified by an official legal opinion, it is reported that such practitioners, who constitute some of the country's leading medical authorities, will merely be required to register their qualifications with the General Bureau of Professions, the government agency which will administer the legislation. Another exception will be made for refugee physicians, who, the statute provides, will be conceded "temporary permits" to practice, provided they are able to "prove themselves to be the victims of political persecution in their own country." Further exemptions will be granted to "professors of specialties still not taught (in Mexico)" or to those "who display unquestionable and outstanding competence," to "consultants or instructors dedicated to the establishment, organization or installation of institutions of public or military instruction, laboratories or institutes of essentially scientific character" and to "technical directors." Following is a partial text of the law:

"No foreigner can practice, in the Federal District and territories, the scientific professions covered by this law.

"Naturalized Mexicans who have conducted all their studies in authorized higher institutions can enjoy the same privileges of professional practice as Mexicans by birth.

"Only in exceptional cases can the General Bureau of Professions, in agreement with the respective institutions and in accordance with legal requisites, grant temporary permission to practice to foreign professional men and women, resident in the Federal District and territories, who prove themselves to be victims of political persecution in their own country.

"Degrees issued abroad to Mexicans by birth can be registered with the Ministry of Education, provided the course of studies leading to the professional degree is the same as or similar to those in institutions recognized by the Mexican government.

"In cases where it is impossible to establish the similarity of the studies, a system of examination will be set up to subject candidates to tests to prove their training.

"Foreigners and naturalized Mexicans who possess a degree in any of the professions embraced by this law must:

"1. Be professors of specialties still not taught or display unquestionable and outstanding competence in the opinion of the General Bureau of Professions.

"2. Be consultants or instructors dedicated to the establishment, organization or installation of institutions of public or military instruction, laboratories or institutes of essentially scientific character.

"3. Be technical directors in the development of the country's natural resources.

"The activities authorized for foreigners and naturalized Mexicans in the foregoing will in any case be temporary.

"The Ministry of the Interior will authorize the entry of foreign professional men and women into national territory, subject to the preceding conditions."

BUENOS AIRES

(From Our Regular Correspondent)

May 24, 1945.

Preventive and Curative Medicine

A law was recently passed giving the Instituto Nacional de Previsión Social charge of administering preventive and medical care to workers and employees who are protected by social insurance. Special attention will be given to patients with chronic diseases of great social importance, such as tuberculosis, cardiovascular diseases, syphilis, rheumatism, industrial diseases and their complications, as well as to industrial invalidism and physical and technical readaptation of workers after illness or accidents. The institute will carry out periodic examination of socially insured workers. No insured worker will be allowed to go without examination for more than one year. An individual clinical record book will be prepared and filed. Workers who are in need of rest will be instructed to reduce the number of working hours or to discontinue work for a certain time. Employers must give workers necessary rest or even a leave of absence for six consecutive months. Employees who are taking a partial or complete rest period will obtain a portion of the regular salary from the employer and the remainder from the Instituto Nacional de Previsión Social. A certain amount will be given to socially insured workers with illness of more than six months' duration. On returning to work an employee is to be given his former job with the regular salary or work better suited to his physical or mental capacity as determined by the institute. Retired invalids are given hospitalization up to a period of not more than six months. When expenses of hospitalization of retired invalids last for several months, 20 per cent of the allowance given to retired workers with a family and 50 per cent of the allowance of retired workers without any family is applied to the expenses of hospitalization. The insured are to obey medical orders. They are not allowed to work with or without payment during a treatment of preventive or curative rest. A budget will be prepared within two years in accordance with expenditures. An insured person is to pay 2 pesos ($0.50) every year for his general medical examination.

Congress of Ophthalmology

The second Pan American Congress of Ophthalmology will be held in Montevideo in November. The officers of the congress are Dr. H. S. Gradle of Chicago, president, Dr. Alberto Vázquez Barrière of Uruguay and Dr. Francisco Belgeri of Argentina vice presidents and Dr. Moacyr E. Alvaro of Brazil executive secretary. At a recent congress in Buenos Aires it was resolved to hold the second congress on Nov. 26, 1945 in Montevideo. Subjects on the program include diagnosis and therapy of preglaucoma, gonioscopy in view of newer knowledge of glaucoma, evaluation and mechanism of destructive effects of ocular hypertension, need of early operation in glaucoma, duration of medical therapy in glaucoma surgery of paralytic strabismus and surgery of heterophoria and concomitant strabismus. Two new topics, contact lenses and gonioscopy, appeared in the most recent program. These subjects will be presented by Drs. Baudilio Courtis of Buenos Aires and H. S. Sugar of Detroit and will be discussed by Drs. D. G. Cogan of Boston and A. Urretz Zavalia of Cordoba. Dr. Alberto Vázquez Barrière of Uruguay will preside. The session on prevention of war will open on the afternoon of November 26. Dr. Francisco Belgeri will preside. Dr. Correa Mayer of Porto Alegre will preside over the session on trachoma.

Dr. Gradle of Chicago recently stated that no ophthalmologic or other scientific news can be reported from Europe because of war conditions. The progress of ophthalmology rests with American centers. Postgraduate studies of the specialty are now receiving proper attention. The Kellogg Foundation offers twenty-five fellowships for postgraduate studies. The second Pan American Ophthalmologic Congress will be a scientific event of great importance to Pan American ophthalmologists. Probably more than one hundred and fifty American ophthalmologists will attend the congress.

Cinematographic Medical Films

Cinematographic equipment was recently obtained by the library of the Faculty of Medicine of the University of Buenos Aires for the purpose of illustrating certain chapters of medicine by means of films. The faculties of medicine as well as other scientific and educational centers of the country will receive copies of the names of the films which are available from the National Center Archivo Gráfico. The films requested from the Archivo Gráfico may be kept at the given educational center as long as they are needed. An apparatus providing the proper phonographic records for the film is lent with the film.

Electrocardiographic Action of Mate Tea

Dr. Enrique Moisset de Espanés recently reported to the Sociedad de Biología of Cordoba the results of electrocardiograms of 15 young men which were taken after ingestion of tea made from 200 Gm. of mate leaves. In the majority of the subjects the voltage of the electrocardiogram increased, especially in the T and R waves and moderately in the P wave. The increase of the voltage persisted in electrocardiograms which were taken one hour after ingestion of the tea.

Control of Exportation of Drugs

A law was recently enacted by the government of Argentina to the effect that custom houses will not permit exportation of drugs without the authorization of the National Department of Public Health. Permits will be issued only when the national needs for the drug in question have been satisfied. Production of certain drugs to be exported will be authorized by the National Department of Health.

Personal Items

Dr. Aloysio de Castro of Rio de Janeiro was recently invited to visit the medical societies of Buenos Aires. The Ateneo de la Historia de la Medicina held an extraordinary meeting in honor of Dr. de Castro, who was appointed honorary member of the academy. Dr. Castro presented to the academy a bust of Dr. Oswaldo Cruz which was made and given by Dr. Phocion Serpa of Rio de Janeiro, and Dr. Castro also awarded to some Argentine members of the academy the diplomas of honorary membership in the Sociedad Paulista de Historia de la Medicina.

Marriages

Robert Jackson Wetmore, Durham, N. C., to Miss Jane Carlton Evans of Washington, D. C., in Chevy Chase, Md., May 11.

Reuben L. Chrestman Jr., Memphis, Tenn., to Miss Deanne Henson of Meridian, Miss., in West Memphis, Ark., recently.

Thomas Fitz-Hugh Jr., Wynnewood, Pa., to Miss Bernice Rowe of Philadelphia in Washington, D. C., March 26.

Mary Charlotte Van Gundy, Beverly Hills, Calif., to Mr. Campbell E. Holmes of Los Angeles, April 5.

Henry V. Guhleman Jr., Jefferson City, Mo., to Miss Mary Florence Laws of Snow Hill, Md., April 7.

William Mahon Myers, Philadelphia, to Miss Jane Louise Mather of Latrobe, Pa., March 17.

Bernard Frank Joseph Fetter to Miss Anna Lee Hinton, both of Durham, N. C., May 11.

Carol H. Konhaus, Mechanicsburg, Pa., to Miss Frances M. Flickinger of Harrisburg, April 21.

Herbert S. Hunter, Latrobe, Pa., to Miss Lois Augusta Anderson of Greensburg, April 6.

Charles F. Taylor to Miss Jeanne N. Klinepeter, both of Harrisburg, Pa., April 1.

Deaths

Charles Goodman ⊕ New York; Western Reserve University Medical Department, Cleveland, 1892; formerly clinical professor of surgery at the University of Bellevue Hospital Medical College; fellow of the American College of Surgeons and the New York Academy of Medicine; member and past president of the Harlem Medical Association; past president of the Eastern Medical Society, the Park West Hospital Medical Board and the Beth Israel Hospital Medical Board; first vice president of the International Medical Club; formerly secretary of the Alumni Association of Mount Sinai Hospital; member of the International Surgical Society, Metropolitan Medical Society, American Public Health Association, Physicians' Mutual Aid Association, Military Order of the World War and the Reserve Officers' Association; volunteered and commissioned a captain in the medical reserve corps of the U. S. Army in May 1917; later organized and commanded a reinforcement group for the Presbyterian Hospital unit abroad, which was General Hospital number 1 of the American Expeditionary Forces; after his promotion to major headed an operating team during the British Expeditionary Force Paschendale offensive; later was director of a field hospital section of the Rainbow division of the American Expeditionary Forces and consulting surgeon to other American divisions; honorably discharged in April 1919; lieutenant colonel, medical reserve corps, U. S. Army, not on active duty; director of the typhus research fund of New York University; consultant in vascular surgery, Veterans Administration; in 1936 a member of the Nobel Prize nominating committee in medicine; for twenty years chief of the surgical division of the outpatient department of Mount Sinai Hospital; consulting surgeon and for twenty years attending surgeon at the Beth Israel Hospital; served as attending surgeon at the Montefiore Hospital, Park West Hospital and the Sydenham Hospital; for two years director of surgery and for two years director of vascular surgery at the Broad Street Hospital; consulting surgeon at the Rockaway Beach (N. Y.) Hospital, Home for Daughters of Jacob and the New York Polyclinic Hospital; member of numerous scientific groups and extensive contributor to the literature; credited with performing in 1906 the first successful blood transfusion; died May 23, aged 73, of heart disease.

Richard Slee, Stroudsburg, Pa.; Long Island College Hospital, Brooklyn, 1891; member of the American Medical Association and the Medical Society of the State of New York; in 1908 among the first to be commissioned in the newly created medical reserve corps of the U. S. Army as a first lieutenant; in 1916 he was sanitary officer at the medical officers training camp at Tobyhanna, Pa.; in command of Camp Crane, Allentown, Pa., 1918-1919; on Sept. 7, 1922 organized and served as commanding officer in charge of General Medical Laboratory number 1, Slee Laboratory Unit at Swiftwater; first National Commander of the United States Army Ambulance Service Association, 1920-1921; colonel, medical reserve corps, U. S. Army, not on active duty; first deputy health commissioner of Westchester County, N. Y., from 1930 to Oct. 1, 1937, when he retired; formerly district health officer of the state health department of New York; at one time assistant bacteriologist and medical inspector, Pennsylvania State Health Department; founder of the Slee Antitoxin and Vaccine Laboratories, Swiftwater; died April 8, aged 78, of cerebral hemorrhage.

Philemon Edwards Truesdale ⊕ Fall River, Mass.; Harvard Medical School, Boston, 1898; member of the founders group of the American Board of Surgery; member of the American Surgical Association, New England Surgical Society and the American Association for Thoracic Surgery; fellow of the American College of Surgeons; served as vice president of the Massachusetts Medical Society; joined the medical corps of the U. S. Army in 1917 and sailed for France with the rank of captain in the Yale Mobile Hospital unit; in October 1918 promoted to the rank of major; on his return to the United States assigned as director of surgery at Camp Devens and honorably discharged on March 15, 1919; member of the House of Delegates of the American Medical Association in 1929; awarded a gold medal in 1929 in the Scientific Exhibit of the American Medical Association for exhibit showing experimental demonstration of the mechanism of transposition of abdominal viscera following rupture of the diaphragm; medical director of the Truesdale Hospital, which he had founded and where he died June 12, aged 70.

Charles Johnson Smith ⊕ Portland, Ore.: Starling Medical College, Columbus, 1888; Bellevue Hospital Medical College, New York, 1890; member of the House of Delegates of the American Medical Association in 1905, 1910 and 1911; past president of the Oregon State Medical Society; for two terms mayor of Pendleton; state senator from Umatilla County from 1902 to 1910; for eighteen years a member of the school board of Pendleton; a member of the Industrial Welfare Commission and chairman of the board of curriculums from 1912 to 1930; one of the organizers and past president of the state board of health; fellow of the American College of Surgeons; for eight years Democratic state chairman for Oregon; president of the Ohio Society of Oregon; surgeon for the Western Division of the Northern Pacific Railroad Company; died April 19, aged 80, of angina pectoris.

William Litterer, Miami, Fla.; Vanderbilt University School of Medicine, Nashville, 1901; formerly professor of bacteriology and assistant professor of preventive medicine and public health at his alma mater, director of laboratories for the Tennessee Department of Public Health for many years; member of the American Medical Association, Tennessee State Medical Association, Southern Medical Association, American Chemical Society, Society of American Bacteriologists and the American Association for the Advancement of Science; did special government research in lethal gas during World War I; died May 1, aged 67, of cerebral thrombosis.

Hyman John Rubenstein ⊕ New York; Tufts College Medical School, Boston, 1927; member of the American Academy of Ophthalmology and Otolaryngology; specialist certified by the American Board of Otolaryngology; Littauer Pneumonia Research Fellow at Harlem Hospital, 1929-1930; served as instructor of otorhinolaryngology at the New York Polyclinic Medical School and Hospital; on the staffs of the Beth Israel and Metropolitan hospitals; consultant to the Home of the Daughters of Israel; formerly on the staffs of the Polyclinic Hospital and the Mount Sinai Hospital, where he died April 30, aged 41, of leukemia.

Earle B. Stokes ⊕ East Orange, N. J.; Jefferson Medical College of Philadelphia, 1914; specialist certified by the American Board of Urology, Inc.; member of the American Urological Association; fellow of the American College of Surgeons; served during World War I; member of the Selective Service System; on the staffs of the Essex County Hospital, Cedar Grove, Essex Mountain Sanatorium, Verona, East Orange General Hospital, Dover (N. J.) General Hospital and the Orange (N. J.) Memorial Hospital, where he died April 29, aged 53, of coronary thrombosis.

Jesse Wolfenden Battershall, Attleboro, Mass.; Tufts College Medical School, Boston, 1916; member of the American Medical Association; since 1925 medical examiner for North Bristol District; served as school physician; since October 1943 health officer; past president of the Medico-Legal Association of Massachusetts and the Doctors Club of Attleboro; director of the Bristol County Health Association; interned at the Robert Brigham Hospital in Boston; on the staff of the Sturdy Memorial Hospital, where he died May 4, aged 51, of embolism following a major operation.

Arnold Frederick Sydow ⊕ Cleveland; Ohio State University College of Medicine, Columbus, 1926; fellow of the American College of Surgeons; demonstrator of surgery at the Western Reserve University School of Medicine; on the staffs of the City and St. Luke's hospitals; physician in charge of the medical staffs at the Cleveland works of the Aluminum Company of America, the Jones and Laughlin Steel Corporation and many smaller Cleveland firms; served on draft board number 30; died in West Palm Beach, Fla., April 28, aged 44, of malignant retroperitoneal tumor.

William Frederick Bennett ⊕ Verona, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1901; in 1923 joined the Essex Mountain Sanatorium, where since 1928 he served as first assistant physician; formerly on the staff of the Pennsylvania State Sanatorium for Tuberculosis in Hamburg, Pa.; died in the Mountainside Hospital, Montclair, May 2, aged 67, of cerebral hemorrhage and suppurative cholecystitis.

Simon William Brownstein, Chicago; Barnes Medical College, St. Louis, 1899; served during World War I; for eighteen years chief of clinics for the city board of health; died May 7, aged 78, of coronary thrombosis.

Orlo Solomon Canright, Columbus, Ohio; Rush Medical College, Chicago, 1884; died May 1, aged 87, of coronary thrombosis.

Etienne Pascal Crowe, Cleveland; University of Wooster Medical Department, Cleveland, 1889; a founder of the Cleveland Academy of Medicine; until his retirement in 1920 had been medical examiner for the John Hancock Life Insurance Company for thirty years; died May 6, aged 86, of disease of the coronary artery.

yellow urine or water, were found to give false positive tests for bilirubin. Since any deep yellow or light red solution exhibits this green color when mixed with methylene blue, there will probably be many more reports on the nonspecificity of this methylene blue test for bilirubin. (See also communication by Watson, Meads and Castle in THE JOURNAL, May 26, p. 308).

THE TERM "WHOLE BLOOD"

To the Editor:—May I presume on your kindness to call to the attention of the members of the medical profession the difference between the term "whole blood" and "citrated blood," also called "modified blood."

The term whole blood is used incorrectly so often when citrated blood is meant that it seems to me that this error should be corrected.

Whole blood and citrated blood are as different as black and white. By far the most important life saving therapeutic agent we have today is properly matched whole blood, and it is my firm conviction that it is never going to be replaced by a substitute.

Citrated blood is a substitute for whole blood, and it should be used only in emergencies and when it is not practical to use whole blood. Severe reactions following the use of citrated blood are far more frequent than when whole blood is used.

Since we adopted the plan to determine the Rh factor on all recipients and give only Rh negative blood to Rh negative recipients, reactions have been eliminated when whole blood is used.

JOHN M. SCANNELL, M.D., Jamaica, N. Y.

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II, July 16-18. Part III. Various centers, June. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF INTERNAL MEDICINE: *Oral.* Chicago, June 27-29. San Francisco, Oct. 15-17. *Written.* Various centers, Oct. 15. Final date for filing application is Aug. 1. Candidates in the armed forces may take the examination at their station with the permission of their medical commanding officer. Asst. Sec., Dr. W. A. Werrell, 1301 University Ave., Madison 5, Wis.

AMERICAN BOARD OF OPHTHALMOLOGY: Chicago, Oct. 4-6; and Los Angeles, January. Sec., Dr. S. Judd Beach, 56 Ivie Rd., Cape Cottage, Me.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: *Part I. Oral and Written.* New Orleans, Sept. 28-29, Philadelphia, Oct. 5-6, Chicago, Oct. 12-13 and San Francisco, Oct. 19-20. Final date for filing application is August 1. Sec., Dr. G. A. Caldwell, 3503 Prytania St., New Orleans 15.

AMERICAN BOARD OF OTOLARYNGOLOGY: Chicago, Oct. 3-6. Sec., Dr. Dean M. Lierle, University Hospital, Iowa City, Ia.

AMERICAN BOARD OF PEDIATRICS: *Written.* Locally, Oct. 19. *Oral.* New York, Dec. 7-8. Sec., Dr. C. A. Aldrich, 115½ First Ave., S.W., Rochester, Minn.

AMERICAN BOARD OF RADIOLOGY: *Oral.* Fall, 1945. Final date for filing application is Aug. 1. Sec., Dr. B. R. Kirklin, Mayo Clinic, Rochester, Minn.

AMERICAN BOARD OF SURGERY: *Written.* Various centers, October 24. Final date for filing application is Aug. 1. Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia 2.

AMERICAN BOARD OF UROLOGY: *Written.* Chicago, Dec. 9. *Oral.* Chicago, Feb. 19-22. Sec., Dr. Gilbert J. Thomas, 1409 Willow St., Minneapolis 4.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Tearing of Esophageal Wall in Attempt to Remove Pork Bone.—The plaintiff swallowed a small pork bone, which became lodged in her esophagus. Within an hour thereafter, because of severe distress, she visited the defendant physician, a general practitioner, for treatment. According to the physician, he first examined her throat by using an illuminated tongue depressor but was unable to detect any foreign body. He then put on a head mirror and with an electric mirror in back and one in front of him and holding the patient's tongue with a sterile pad he thought he detected a foreign body in the throat. By means of a pair of laryngeal forceps about 10 inches long, with a piece of surgical cotton on the end, he proceeded to try to wipe this foreign body from the throat with a sweeping motion from below upward. He was unsuccessful in removing it and informed his patient that he could do nothing further and that the case was one for a specialist who could use an esophagoscope. He then called Dr. Carmody, a specialist, who instructed him to take roentgenograms and to send the patient to a hospital where the specialist could attend her. The defendant physician testified positively that he did not insert the forceps down the patient's esophagus and that it would have been physically impossible for his forceps to have reached the spot in the esophagus where Dr. Carmody testified he found the pork bone—namely, on the left side of the esophageal wall about opposite where the first rib makes a junction with the clavicle. The plaintiff and her husband, on the other hand, testified that the forceps the physician claimed he used and which were introduced in evidence were not the instrument used by the defendant. Their testimony seemed to indicate that the defendant wrapped some cotton around the end of a probe, which seemed about 14 inches long, longer than the forceps the defendant claimed he used, and that the defendant then put the instrument down the plaintiff's throat as far as he could. According to the plaintiff, the use of the probe "caused a sharp pain. Then the bone in my throat slipped. I didn't have that choking. Then he took the probe out and went over and wrapped it with cotton again" and then said if he was unsuccessful he would have to resort to a specialist. Prior to the defendant's operations, so the patient testified, there had been no hemorrhage but about the time she left his office to go to the hospital—approximately ten or fifteen minutes after the probing—some hemorrhage occurred. Dr. Carmody, the specialist, testified that later in the night in question by means of an esophagoscope he located and removed the pork bone. This operation involved placing the patient under an anesthetic and then inserting the instrument gradually down the esophagus. Basically, the instrument is a hollow tube within which run two wires; at the end of one of these is a small electric lamp with which the operator, by means of a reflector, can see the area just ahead of the esophagoscope; at the end of the other wire is a set of diminutive forceps with which the operator may take hold of objects. Dr. Carmody stated that he first located some cotton on the left side of the esophageal wall, about opposite where the first rib makes a junction with the clavicle, and that it was the cotton that led him to the foreign body. "I couldn't," he said, "see the foreign body. I saw the cotton. The cotton was on the foreign body. . . . The bone came out with it." Subsequent examination disclosed a tear in the esophageal wall and the bone or cotton, at the time of its removal, was inside, and not outside, the wall. No damage apparently was occasioned by the use of the esophagoscope itself. On account of the tear in the esophagus, the patient became ill; fluid developed in the pleural cavity; mixed infection—streptococcus empyema and also staphylococcus—occurred, and it was necessary to resort to liquid feeding for two weeks to prevent any solid food material working into the pleural cavity. Drainage of that cavity became imperative and the drainage tube remained in her side for approximately three months.

Subsequently the patient instituted an action for malpractice against the defendant physician, alleging apparently that the tear in the esophageal wall and her subsequent disability was occasioned by his negligence. At the trial, in addition to the testimony of the patient and her husband, the defendant physician, and Dr. Carmody, there was medical testimony that the piece of surgical cotton which was firmly adhering to the bone at the time of its removal by Dr. Carmody might have been swallowed by the plaintiff during the procedures instituted by the defendant and in its journey down the esophagus might have come into contact with the bone and adhered thereto There was also medical testimony that the adherence of the cotton to the bone was so firm that the impact between the bone and the cotton must have been with more force than that involved in the act of swallowing. Although the defendant physician had testified that the plaintiff complained of the foreign object being in the upper reaches of the throat, Dr. Carmody testified that when the defendant physician telephoned him he stated that he had a patient in his office who had a bone in her esophagus Several medical witnesses, called by the patient, in answer to hypothetical questions, testified that, assuming the existence of a bone in the esophagus and a probing for it in a manner related by the patient, such a procedure was not good medical practice under present standards in the profession for a general practitioner and would be dangerous to the patient. The defendant's evidence went to the point of showing that he did not insert any instrument in the patient's esophagus; that the forceps he used did not and could not reach beyond the cricoid constrictor located at the entrance to the esophagus, while the plaintiff's evidence went to the point that without preliminary examination, either by way of x-ray or esophagoscope, the defendant physician introduced a probe into the patient's esophagus causing the injury described. After a series of motions the court submitted the case to a jury, which returned a verdict in favor of the patient and judgment was entered thereon. The defendant physician appealed to the Supreme Court of Colorado.

The defendant physician at appropriate times during the trial moved for a nonsuit, directed verdict and for a new trial, all of which motions were denied. These motions, said the Supreme Court, involved the one question as to whether or not there was sufficient competent evidence to warrant the submission of the case to the jury. We believe that there was and the trial court's denial of the motions was proper.

The following instruction was given by the trial court to the jury:

> You are instructed that in judging the proper degree of skill to be exercised by a physician or surgeon in any given case, regard is to be had to the advanced state of the profession at that time, and that a physician or surgeon by holding himself out to the world as such impliedly contracts that he possesses the reasonable degree of skill, learning and experience which good physicians and surgeons of ordinary ability and skill, practicing in similar localities, ordinarily possess, and that he will use his skill with ordinary care and diligence according to the circumstances of the case, and if you find that the defendant in this case did not use ordinary care and diligence then you will find for the plaintiff.

The defendant contended that this instruction was improper because it failed to state that the defendant, as a general practitioner, was not expected to have or to exercise the skill of a specialist in treating cases of the kind involved here. This instruction, answered the court, is a proper one as relating to a physician in general practice. The standard to which he is held is ordinary ability and skill to be applied with ordinary care and diligence according to the circumstances of the case There is nothing in the language of the instruction complained of suggestive of a specialist.

The physician complained of the instruction just quoted on the additional ground that it contained no statement that to justify a finding for the patient there must, in addition to a finding of lack of ordinary care and diligence on the part of the physician, also be a finding that such lack of ordinary care and diligence was the proximate cause of the injuries complained of. This instruction, said the court, was proper when read in connection with all the other instructions, including one instruction which is a standard instruction relating to the burden of proof and still another instruction which stated that a physician "does not warrant success and is not responsible for want of success unless that want results from failure to exercise that reasonable care, diligence and skill" previously referred to in instructions tendered the jury.

The court accordingly affirmed the judgment in favor of the patient.—*Dixon v. Norberg, 157 P. (2d) 131 (Colo., 1945).*

MISBRANDED PRODUCTS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the Federal Security Agency

[EDITORIAL NOTE—These Notices of Judgment are issued under the Food, Drug and Cosmetic Act, and in cases in which they refer to drugs and devices they are designated D.D.N.J. and foods, F.N.J. The abstracts that follow are given in the briefest possible form. (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the date of shipment; (4) the composition; (5) the type of nostrum; (6) the reason for the charge of misbranding, and (7) the date of issuance of the Notice of Judgment]

Allan's Red Wash Combination.—Allan & Co, Inc, St Louis, and John G Ayars Shipped between Sept 18 and Oct 1, 1941. Consisted of a bottle of "Red Wash" and one of "Sa Ura Emulsion." The "Wash" was essentially small amounts of cresol, boric acid, glycerin, water and compounds of aluminum, ammonium and zinc sulfates The "Sa Ura Emulsion" contained chiefly castor oil and volatile oils, including sandalwood, turpentine and balsam of copaiba Both products misbranded because falsely represented as effective in curing, mitigating, treating or preventing social diseases—[*D. D. N J., F. D. C 855, May 1944*]

Be Plex Vitamin B Complex with Minerals and Iron.—Hale Drug Company, Birmingham, Ala. Shipped Jan 9, 1942. Composition: product contained not more than 25 per cent of the 669 International units of vitamin B_1 per fluid ounce declared on label. Adulterated for this reason Misbranded because of false and misleading label representations that in cases of vitamin deficiency product would be valuable as an aid to promote appetite and a protection to the body against "nerve disorder," and a help in certain cases of retarded growth, constipation, migraine, head aches and some other things, whereas it would not be efficacious for such purposes—[*D. D N J, F. D. C. 878, May 1944*]

Crab Orchard Concentrated Mineral Water.—Crab Orchard Mineral Water & Crystal Company, Inc, Crab Orchard, Ky Shipped March 23, 1940. Composition: dissolved mineral matter, chiefly magnesium and sodium sulfates, with smaller amounts of other salts Misbranded because labeling falsely represented that the water would be an effective treatment and alleviation of conditions usually calling for a sojourn at a mineral spring, that it would relieve inveterate chronic diseases, cleanse the system of toxins and waste matter, and remove the dangers of constipation; that it would benefit conditions arising from disordered liver and kidneys, prevent attacks on the blood corpuscles by toxins engendered in the system from defective filtration or cleansing; that it would prevent depletion of the nerve cells, safeguard beauty in women and keep men fit; that it would be beneficial in treating constipation, rheumatism, headaches, influenza, colds and some other disorders, keep the blood stream pure, help skin blemishes and eruptions, maintain a clean system, improve the appetite and enable one to sleep and feel better—[*D. D. N. J., F D C. 889, May 1944*]

Glendage—Joseph A. Piuma, Los Angeles Shipped August 1, 1941. Composition: tablets, each containing glandular material, including ½ grain of thyroid, with nux vomica extract (containing strychnine), a phosphide such as zinc phosphide, and a laxative drug, such as cascara sagrada extract Misbranded because of false representation of glandular substance present, since such substances were not physiologically or therapeutically active when taken by mouth as directed—[*D. D. N. J., F D. C. 890, May 1944*]

McBrady's Hair Pomade—Bernard McBrady, trading as J. E McBrady & Company, Chicago Shipped July 28 and 29 and Dec 12, 1941 Composition: essentially a small amount of a fatty acid such as stearic acid, incorporated in a base of petrolatum and wax. Misbranded because label falsely represented that product was an effective cure or preventive of stubborn and falling hair, would give the hair a better chance to grow, cause it to grow faster, and soften and limber it—[*D. D. N. J., F. D C. 887, May 1944*]

Real's Antiseptic Medicated Skin Cream—Baker Drug Corporation, Norfolk, Va Shipped Feb 12 and March 21, 1942, the earlier shipment being made in the name of Joseph Friedberg Composition essentially small amounts of potassium hydroxide, volatile oils, including menthol, eucalyptol and oil of bergamot, and a trace of phenol in a base of stearic acid, petrolatum and beeswax Bacteriologic examination showed article devoid of antiseptic properties Adulterated because strength and quality fell below represented antiseptic standard, and misbranded for the same reason—[*D D N. J, F D C 864, May 1944*]

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Relationship of Normal and Hyperactive Ovary to Menstruation and Endometrial Hyperplasia. C. G. Hartman.—p. 99.

Cushing's Syndrome.—Cluxton and his associates report the clinical history and necropsy of a woman, aged 27, who came to the Mayo Clinic presenting most of the features of Cushing's disease. The absence of adenomas, neoplastic or hyperplastic changes in the pituitary body, thymus or adrenal cortices and the associated alkalosis that was present during the life of the patient are elements of additional interest. The patient's illness could not be attributed to any demonstrable anatomic abnormality if one excepts the hyaline changes that were found in the basophilic cells of the anterior lobe of the pituitary body. The physiologic significance of these changes is not known, but one of the authors believes that these changes are secondary or retrograde rather than an alteration of fundamental significance in the causation of the syndrome and that the clinical manifestations of the patient's illness were an expression of an abnormal adrenal cortical function of a hypersecretory character in spite of the fact that there was no histologic evidence to support this view. This case also presents one more instance of alkalosis and low potassium occurring in Cushing's syndrome, 3 cases having been previously reported from the Mayo Clinic. In some cases alkalosis occurs solely as the result of abnormal adrenal cortical function.

Diabetic Neuropathy.—Rudy and Epstein review 100 cases of diabetic neuropathy followed from one to ten years. The incidence according to clinical localization was neuritis 54, myelopathy 26, encephalopathy 4, encephalomyelopathy 5 and neurogenic bladder disturbances 11. Diabetic neuropathy is a generalized neurologic disturbance. It is observed not only in the acute stage of diabetes but also soon after the control of the glycosuria and hyperglycemia and in the chronic and even mild cases of diabetes. This neuropathy develops most frequently in patients over 50 years of age and is preceded or accompanied by considerable loss of weight. Symptoms and signs of a vitamin B complex deficiency are frequently associated with it. The vitamin deficiency is secondary, and it appears to be caused by the disturbed metabolism and at times by an associated chronic infection or other complication. A demonstrable dietary insufficiency is a factor only in certain cases. Complete recovery from the neuropathy is uncertain and slow, but it occurs following prolonged therapy with vitamin B and control of the glycosuria and hyperglycemia.

Treatment of Malaria.—According to McCoy, atabrine has proved much more effective than quinine for suppression of malaria and, in general, is better tolerated and preferred by troops. A most important experience gained is the demonstration of the effectiveness of atabrine in preventing the development of falciparum malaria. When atabrine is taken in doses of 0.6 or 0.7 Gm. per week during and for several weeks following exposure to falciparum infection, appearance of symptoms is consistently prevented not only during suppressive treatment but also after medication is discontinued. Suppressive doses of atabrine apparently act as curative doses in this type of malaria. In this respect atabrine is far superior to quinine. As a result of the extensive use of atabrine for suppressive treatment, falciparum malaria has been much less of a problem in the military forces than was anticipated at the start of the war. Vivax malaria, on the other hand, is suppressed but not cured by atabrine. Relapses of vivax malaria experienced after the cessation of suppressive medication constitute a major portion of the Army's malaria problem. In units heavily seeded with vivax malaria it may be necessary to continue suppressive treatment in order to maintain military effectiveness even though no further exposure to infection occurs.

Importation of Exotic Anophelines.—According to Mulrennan and his associates the present emergency has greatly increased the possibility of exotic species of insects gaining ingress and becoming established in North America. This can be partially demonstrated by the fact that alien anophelines have been collected in two localities in Florida, with the infer-

ence on aircraft importation, since the specimens were collected adjacent to air fields. Emphasis is placed on the insecticiding of aircraft at the port of debarkation and a second application and inspection at the port of entry.

Patient's Reaction to "Lunacy" Charge. L. Kerschbaumer.—p. 378.

Hemiballismus.—According to Kelman, hemiballismus is a syndrome characterized by violent uncontrollable, purposeless, throwing (ballistic) movements of one upper extremity or of the entire half of the body. The lesions in the corpus luysi are mainly due to hemorrhages, softenings or emboli, but they may also be due to infections, toxins and degenerative conditions. The author presents the clinical and pathologic aspects of 2 cases of hemiballismus. The first patient, a man aged 66, died within three months of the first attack. The episodic nature of the attacks suggests that they were due to an irritative process within the corpus luysi. In this case a destructive lesion was found. The destructive process is evidence of the previous existence of a dysphysiologic state. Such transitory states might occur and lead to attacks of hemiballismus without leaving significant evidence in the form of cellular changes in the corpus luysi or of degeneration in its afferent or efferent tracts. The nature of the attacks, at times involving only the hand, at others including also the face, finally to affect the lower extremity, confirm clinically that somatotopic localization exists in the corpus luysi. The second patient, a man aged 56, lived eight months after the onset of the abnormal movements. It has been stated that volition and psychic factors do not affect the movements. When this man was at rest the movements were least. When he made attempts to use his extremities spontaneously or on command as well as when he became emotionally disturbed, the movements became exaggerated. Neither of the 2 patients could voluntarily control the movements. In the second patient a metastatic nodule invaded and destroyed the tip of the oral pole of the corpus luysi. At necropsy the major lesion was so placed as to affect essentially the subthalamicotegmental fibers. This seems to indicate that a lesion limited to afferent tracts might cause hemiballismus. It also tends to prove the passage of most of the fibers contralaterally but also indicates that some pass homolaterally. The major movements were on the right side, but some were also present on the left.

Intraspinal Thiamine Hydrochloride in Tabes Dorsalis.—Kesert and Grossman say that in 1942 Stone reported good results from the use of intraspinal and oral vitamin B in cases of tabes dorsalis. Not only were the shooting pains in tabes relieved, but improvement in gait, bladder control and muscular tone was noted. The authors proceeded to try this form of therapy in all of their cases of tabes dorsalis, mainly for relief of shooting pains and gastric crisis. Up to the present, 8 patients have been followed. They were given from one to six intraspinal injections in doses ranging from 50 to 100 mg. The pains were intensified for a period of twelve hours after the injection, but then relief followed, which was partial or complete and lasted from several weeks to months, sometimes longer. Some of the patients were receiving thiamine hydrochloride orally or subcutaneously, but immediate relief of the intractable pains was due to the action of the thiamine hydrochloride given intraspinally. The use of narcotics and chordotomy can be avoided when thiamine hydrochloride is injected for tabetic and gastric crises.

Dietary Vitamin C and Physical Well Being of Manual Workers.—Johnson and his associates report experiments conducted during the summer in Civilian Public Service Camp 32, Campton, N. H. The 24 volunteer subjects were engaged in a variety of jobs associated with the work schedule of the camp, which included clerical work, kitchen work, camp maintenance, farming, clearing trails and road building. The range of daily caloric expenditures, depending on the subject's job, was estimated to be 2,400 to 5,000. There were four groups of subjects. The "deficient group" was to demonstrate the effects of total deficiency, the "supplemented deficient group" the effects of 75 mg. of ascorbic acid daily, the "normal control group" the effects of a good normal diet and the "supplemented normal control group" the effects of a normal diet supplemented with 75 mg. of ascorbic acid daily. If the previous diet has been good, total deprivation of vitamin C for two months does not lead in manual workers to detectable deterioration in physical vigor, to inefficiency in the day's work or to unpleasant symptoms, provided the daily diet is adequate in all nutrients other than vitamin C. Such deprivation may occasionally lead to minimal changes in the gums and does produce severe desaturation as measured by serum and urinary levels of vitamin C and by tolerance tests. When given in doses of 25 mg. three times daily, 75 mg. of ascorbic acid a day appears adequate to maintain or even to increase the body stores of the vitamin in a majority of men held for two months on a diet totally deficient in ascorbic acid. Supplements of 75 mg. of ascorbic acid a day when added to a good normal diet are of no detectable benefit to manual workers over a period of two months with respect

to general well being, physical vigor for hard work and efficiency in the day's work. Such supplements do lead to increased stores of vitamin C, as evidenced by serum and urinary levels and by tolerance tests.

*Blood Plasma in Treatment of Encephalitis Lethargica and Polioencephalitis: Preliminary Report. P. Nicholson.—p. 298.

Salicylate Therapy in Acute Rheumatic Fever.—Wégria and Smull compared the course of acute rheumatic fever in two groups of patients, one "adequately" treated according to Coburn's standards and one with smaller doses. In the adequately treated group the serum salicylate levels ranged between 350 and 500 micrograms. The other group received such doses of salicylate that serum levels in most patients were constantly below 250 micrograms per cubic centimeter and in a few patients reached "optimal" levels only for short periods. The course of the disease was not shorter in the adequately treated group.

Blood Plasma in Treatment of Encephalitis.—Nicholson reports a case of lethargic encephalitis and a case of polioencephalitis in both of which pooled adult plasma was given intravenously with favorable results. He suggests that this method of treatment might be used in epidemics of poliomyelitis, because the case presented here was one of a severe encephalitic type and gave the use of blood plasma a severe test.

Penicillin for Gonococcic Vaginitis of Children.—Swe and Putnam used the sodium salt of penicillin in the treatmer of 15 children with gonococcic vaginitis, 1 with vaginitis an conjunctivitis and 1 with conjunctivitis. The diagnosis in 1 cases was established by culture. The penicillin was given i multiple injections over a period of from twelve to twenty seven hours. The exact schedule of dosage remains to be determined, but the authors think that children of 7 years or under probably will respond to a dose of 50,000 units given over twelve hours, while older patients should be given approximately 100,000 units of penicillin. A single large dose of regular sodium penicillin is not effective, although it is possible that two or three injections of 25,000 to 50,000 units each at intervals of two or three hours may be curative. This regimen will be investigated, since, if satisfactory, it would greatly simplify the office or clinic treatment of such patients.

Penicillin in Leprosy.—According to Faget and Pogge, penicillin was tried at the National Leprosarium in the treatment of 7 cases of leprosy in doses of 50,000 to 100,000 units daily, which were continued in some cases for a month's time. No specific beneficial effect could be attributed to this treatment. Subsequently two of the previously treated patients and 2 new patients were given much larger doses of penicillin without effect.

Roentgenotherapy in Inflammatory Lesions.—Dufresne says that experimental studies justify the conclusion that x-rays in small doses activate the proliferation of lymphoid tissues, augment the mobilization of lymphocytes, increase the bacteriolytic power of the blood and improve the local defense. His clinical experiences with x-rays cover a period of fifteen years. The majority of acute infections in which Dufresne has employed roentgenotherapy have been superficial, such as ery-

sipelas, furunculosis, anthrax, sycosis and herpes zoster. The only cases of deep acute infections in which irradiation was used were pelviperitoneal ones associated with cancer of the uterus. The number of subacute and chronic infections treated with x-rays has been comparatively larger than that of acute infections, they include among others acne, mycosis fungoides, cholecystitis, rectitis, adenitis, tuberculous adenitis and epididymitis, poliomyelitis, myositis and osteoarthritis. In acute infections two or three small doses of from 25 to 75 roentgens each are usually sufficient to abort the attack. In subacute infection six to eight doses of from 100 to 125 roentgens each are administered at intervals of two or three days. In chronic infections irradiations extend over a long period and may reach a total of from 2,000 to 2,500 roentgens. The more superficial the infection, the lower should be the voltage and the lighter the filtration, the deeper the infection, the higher should be the voltage and the stronger the filtration.

Tsutsugamushi Fever.—Berry and his associates present the clinical aspects of tsutsugamushi fever among 195 patients admitted to two station hospitals in New Guinea between December 1942 and June 1944. Eighty-five of these patients were admitted directly to the hospitals early in the course of their illness, the remainder were transferred from other hospitals for convalescent management. They stress that tsutsugamushi fever is an acute infectious systemic disease in which the most striking features are pronounced toxemia and widespread damage to the capillaries and arterioles. The physician may be inclined to attribute low blood pressure, cyanosis and tachycardia to myocardial failure when in fact they are due to peripheral vascular collapse. The clinical picture is more analogous to shock than to heart failure. Clinically there is no severe irreversible damage to the myocardium. The asthenia and tachycardia which occur in convalescence are no more pronounced than those which may be expected to follow any prolonged severe illness. One must carefully avoid giving the patient the impression that he has heart disease, because in patients with psychoneurotic tendencies a "cardiac neurosis" may result, and when this occurs it is extremely difficult to return the patient to duty. Although the pathognomonic pulmonary lesion is vascular, atelectasis is of clinical importance and occurs more frequently than has been recognized and apparently is secondary to the pneumonitis and bronchiolitis that are part of the disease. The rapid shallow respiration which one sees in severely ill patients is of pulmonary rather than cardiac origin. The pathologic changes found in the brain and leptomeninges, like the myocardial changes, are reversible, and if the patient survives his illness permanent sequelae are not to be expected.

Cardiac Complications of Tsutsugamushi Fever.—Levine says that an investigation of the cardiovascular status of 130 patients convalescent from tsutsugamushi fever, made at a United States Army general hospital, showed no evidence of persistent myocardial damage. In its effect on the heart this disease seems to resemble diphtheria. If the patient survives the acute phase his heart eventually shows complete return of function. The disability following the acute phase of the disease is largely that of neurocirculatory asthenia. The disease is associated in its acute phase with a generalized vasculitis, which is followed by a state of poor vascular tone. The latter, rather than cardiac involvement, is believed to account for the poor response to exercise in the convalescent stage.

Typhoid in Immunized Subjects.—Tullis states that protection against typhoid by immunization is relative. The typhoid he observed in the 7 previously immunized subjects was atypical and difficult to diagnose. Abdominal pain was a prominent admission complaint. The Widal test was of limited diagnostic value, owing to the universal immunization of all subjects. Four patients in whom falsely positive (anamnestic) reactions were repeatedly demonstrated were also studied. The presence of a rising titer of agglutination was of no aid in differentiating the true from the false positive Widal reactions. Separation of the agglutination into the flagellar and somatic fractions was of limited diagnostic import. Positive flagellar agglutination occurred in both the patients with and the patients without typhoid. Somatic agglutination occurred in only the patients with typhoid. The clinical course seemed mild; the complication rate, however, was high. Complications included (1) transient icterus, (2) colon bacilluria, (3) clinical relapse and (4) perforation of the gallbladder, with peritoneal abscess formation and peritonitis. The treatment of all patients was symptomatic and consisted in high caloric diet and good nursing care. The recovery rate was 100 per cent.

Heart Failure Following "Blast Injury."—In the Italian campaign the majority of blast injuries in patients admitted to evacuation hospitals were due to land mines and high explosive shells, while only a small percentage developed from bombs. Most of these men had penetrating wounds, usually compound fractures of an extremity. Leavell observed 3 patients with blast injury presenting unexplained heart failure. All 3 were healthy young adults who had performed strenuous work until they were wounded. In none was there evidence of valvular disease, hypertension, renal disease or urinary suppression. The amount of fluid administered parenterally did not appear to be excessive. The fact that all 3 patients received a blast injury at the time of wounding and that heart failure developed several days later suggested the possibility that the two might be related. In an attempt to determine the factors responsible for the heart failure 35 other patients with blast injury were studied from a cardiovascular point of view. Two of these had abnormal venous pressures without obvious cause, and 3 additional

patients manifested electrocardiographic abnormalities. No adequate explanation can be offered for these observations. It is suggested that, when pulmonary edema develops following blast injury, digitalization and venesection may be indicated.

Stability of Penicillin in Solution and Ointment.—Gots and Glazer studied the activity and stability of penicillin in solution and in ointment bases by means of modifications of the agar plate assay and the serial dilution turbidity method. A solution and ointments of penicillin containing equal numbers of units showed practically the same activity. When the solution and the ointments were kept at refrigerator temperature there was no significant loss of activity at the end of sixty days. At room temperature and at incubator temperature there was complete loss of activity in approximately a month.

Visceral Leishmaniasis in the Armed Forces.—Burchenal and Woods draw attention to the occurrence of kala-azar among troops returning from the Mediterranean area. Kala-azar is characterized by the invasion of the reticuloendothelial system by a protozoon parasite, Leishmania donovani. The symptoms are long continued fever, oftentimes with a double daily elevation of temperature, and progressive splenomegaly followed by hepatomegaly, loss of weight, leukopenia and anemia. Generalized lymphadenopathy is occasionally noted. The authors present the histories of 3 patients whom they treated during the past three months. The first case is notable for the acuteness and severity of the disease and of the difficulty in establishing the diagnosis by demonstration of the parasite. The second shows a more chronic course but again illustrates the difficulty in finding the parasites. The third case presents an entirely different clinical picture, with moderate enlargement of the posterior cervical lymph nodes as the only sign of the disease. The first 2 patients responded to what is usually considered adequate treatment, but both relapsed shortly thereafter and required further therapy. The third patient is still undergoing treatment. Sternal aspiration is probably the safest method of demonstrating the leishmania parasites and should be tried first, but in some cases it may be necessary to resort to splenic puncture. Early diagnosis and institution of treatment before the occurrence of granulocytopenia is most important. Visceral leishmaniasis was first treated with antimony and potassium tartrate, and this agent may still be used where less toxic drugs are not available. The pentavalent antimony derivatives, such as neostibosan, neostam and sodium antimony gluconate, are less toxic.

Sodium Penicillin in Sulfonamide Resistant Gonorrhea.—Horn and Cowper administered penicillin to 71 women with gonorrhea. All except 1 had received but had failed to respond to one or more courses of sulfonamide treatment. The remaining patient had been started on penicillin because she had nonspecific hepatitis. The sodium penicillin was administered at three hour intervals by intramuscular injection in sterile distilled water or in isotonic solution of sodium chloride. The individual doses varied between 20,000 and 50,000 units and the total doses ranged from 100,000 to 200,000 units. More than one fifth of the women failed to respond to the penicillin therapy. Among the 43 women who had involvement of only the lower genital tract 5 failed to respond to penicillin, but of the 31 with associated upper genital tract infection 11, or more than a third, failed to respond. The authors also observed the trend that the older was the infection, the poorer was the chance of success with penicillin in the dosages used. They stress that early diagnosis and early institution of penicillin therapy are paramount considerations in the control of gonorrhea. In the female, in whom diagnosis and cure are difficult to establish and time consuming, delay caused by a preliminary trial with the sulfonamide drugs may diminish the possibility of cure.

Skin Eruptions from Local Application of Sulfonamides.—Peterkin directs attention to the skin eruptions that have been known to follow the local application of the sulfonamides. He observed a number of these cases in 1942 in England and 65 cases in North Africa in 1943, many of them of much greater severity than those seen in England. In 61 of the 65 cases sulfanilamide powder was the first sulfonamide drug to be applied. The eruption is invariably preceded by application of the powder, and it is suggested that the patient becomes sensitized to the drug by its inhalation. It is recommended that powdered sulfonamides should not be applied to the skin for minor conditions. Over 200 patients, including 183 with impetigo or impetiginized seborrheic dermatitis, were treated in North Africa with 5 per cent sulfathiazole in Lassar's paste or Lanette wax cream, and the skin freely exposed to light. Only 1 patient (with respirator dermatitis) developed an eruption; this was mild and soon subsided. It is considered that 5 per cent sulfathiazole in a suitable base is probably as safe as ammoniated mercury for dermatologic therapy and gives better results.

Inguinal Hernia in Merchant Navy: Analysis of 200 Consecutive Cases. P. P. Cole.—p. 296.

Cross Infection Risks in Hospitalization of Patients with Measles.—Wright found that almost three fourths of 65 patients with measles in one group became cross infected with type 6 hemolytic streptococci. Twelve of these patients developed middle ear suppuration and 4 were subjected to mastoid operations. More than a fourth of the patients developed skin infections, mainly impetigo. In another group analysis was made of the occurrence of middle ear suppuration among all the patients with measles hospitalized between December 1942 and May 1943. Among 496 patients 3.6 per cent suffered from "early" and 13.3 per cent from "late" middle ear suppuration. In view of the findings in the first investigation it could be assumed that the great majority of the late middle ear complications were due to cross infection. The late middle ear suppuration rate was considerably lower among patients admitted in April and May than among those admitted in the winter months. The percentage incidence of ear complications was not higher among children under 3 years of age, but the seriously damaging effects of cross infection fell most heavily on them. Of the 238 children in this group, 11 underwent mastoidectomy and 1 died. Infants under 1 year of age suffered particularly severely; 6 of the 45 infants developed late middle ear suppuration, and in 4 cases this was followed by further complications. In view of the high complication rate due to cross infection, treatment at home rather than in the hospital is advocated for patients with uncomplicated measles. For the

protection of measles patients who must be admitted to the hospital recommendations are made for the control of cross infection and for improvements in administrative and nursing procedures.

Ammonium Chloride for Experimental Nephrosclerosis.—Selye and his associates point out that desoxycorticosterone acetate produces nephrosclerosis and hypertension in many animal species, especially if given to unilaterally nephrectomized animals kept on a high sodium chloride intake. The authors report experiments on rats which indicate that ammonium chloride is highly effective in preventing some of the most serious toxic effects of overdosage with desoxycorticosterone acetate. Since there is reason to believe that nephrosclerosis with renal hypertension, periarteritis nodosa and perhaps also some of the manifestations of "rheumatic fever" are due to intoxication with excessive amounts of an endogenous cortical substance resembling desoxycorticosterone acetate, it seemed desirable to examine the efficacy of ammonium chloride in patients with such diseases. This salt may also make it possible to use desoxycorticosterone acetate more extensively in adrenal cortex deficiency without incurring the danger of overdosage. This would be a new application of a remedy which has been used in large doses as an expectorant and diuretic and would not necessitate the extreme caution necessary with a new drug.

Mite Borne Typhus in Anglo-Egyptian Sudan. R. W. Stephenson.—p. 341.

Decortication in Clotted and Infected Hemothoraces.—According to Thomas and Cleland, hemothorax is by far the commonest complication in chest injuries. The compound hemothorax which is associated with injury to the lung, diaphragm or chest wall requires surgical treatment, and the associated hemothorax if removed at the time of operation rarely causes further serious trouble. The simple hemothorax presents a different problem. Its mortality and morbidity depend almost entirely on infection or clotting. The increased incidence of massive clot formation observed in casualties from the Western European campaign may possibly be due to the employment of intrapleural penicillin, but in vitro experiments have lent no support to this view. The extensive use of intrapleural penicillin has unfortunately been associated with a tendency to disregard the principles of early and frequent aspiration of blood from the pleural cavity, so that many cases remain virtually unaspirated for a considerable period. An additional factor may be the high proportion of mortar wounds resulting in increased tissue damage. Among the 750 patients with chest injuries observed by the authors, 526 had hemothoraces. Of these, 30 per cent became infected and in 9 per cent clotting resulted. Earlier methods of treating clotted hemothoraces were attended by incomplete or considerably delayed lung expansion; at the best such methods led to considerable respiratory embarrassment. Less fortunate cases were left with severe and prolonged pleural infection. The employment of decortication with suction drainage fulfils the basic principle of early and complete reexpansion of the lung. Results in a limited series of hemothoraces have been considerably better than those of earlier procedures. A small series of both drained and undrained empyemas following hemothoraces have also been treated successfully by decortication and suction drainage.

*Hemiaplasia of Thyroid Gland. H. R. G. Poate and S. L. Spencer.—p. 223.
*Case of Chronic Solid Subdural Hematoma. R. A. Money.—p. 224.

Hemiaplasia of Thyroid.—Poate and Spencer report 2 cases of hemiaplasia of the thyroid. The anomaly occurs often enough to require the surgeon to expose both sides before beginning a thyroidectomy. The danger of inadvertently removing the patient's entire thyroid tissue is increased by the fact that in the great majority of cases of hemiaplasia it is the left lobe which fails to develop. In both of the cases recorded here the left lobe was lacking. As it is almost universal practice in thyroid surgery to begin on the right side, the operator may detach this lobe from its vascular supply before becoming aware of the absence of the left lobe.

Solid Subdural Hematoma.—According to Money, solid subdural hematoma is rare. A man aged 23 presented symptoms suggestive of the presence of a cerebellar tumor on the left side. Preparations were begun for an exploratory suboccipital operation. As a preliminary step, burr holes were made in the skull over both occipital lobes. On the left side the dura mater was thick and discolored, and, when it was cut through, brown fluid and old liquid blood escaped, indicating the presence of an old subdural hematoma. About an ounce of liquid was evacuated by lavage and suction, with immediate relief of symptoms, and a small piece of corrugated rubber was inserted in a forward direction. It was hoped that the remainder of the hematoma would drain out this way. After the discovery of the hematoma, the patient recollected that about the end of March 1942, while playing soccer, he had received a blow or kick on the head, which knocked him down. He continued the game for at least half an hour in a dazed condition; yet this minor injury must have been sufficient to tear one of the cerebral veins entering the sagittal sinus and start bleeding into the subdural space. Later the patient had a generalized epileptic seizure; the headaches persisted and papilledema increased. These and other observations made it obvious that a large, probably clotted and organized subdural hematoma was still present. After a large osteoplastic flap had been raised and the thickened dura reflected, a substance having the appearance of liver was encountered in all directions. This liver-like mass represented a solid subdural hematoma. The patient made a good recovery.

*Sulfonamide in Therapy of Trichomoniasis Vaginalis. A. Alexander. —p. 248.

Sulfonamide Therapy of Trichomoniasis Vaginalis.—Alexander describes the local sulfonamide treatment of 26 patients with trichomoniasis vaginalis. The vagina was washed with 1 liter of boiled water and was cleansed with sterilized gauze, a sulfonamide tablet was placed in each cul-de-sac and the vagina was tamponed with gauze. The treatment was repeated on five or six consecutive days. The discharge, the vulvar pruritus and the burning local sensation disappeared after the first day in the course of the treatment. The permanent disappearance of the flagellum was verified by microscopic examination of the discharge.

Electrocoagulation of Gasserian Ganglion.—Bauer reports experiences with electrocoagulation of the gasserian ganglion in more than 500 cases of neuralgia. There was not a single fatality. Injection of procaine hydrochloride solution is made to infiltrate the track for the puncture cannula to the base of the skull. A 12 cm. long, thin cannula insulated with celluloid is introduced and is passed slowly forward along the foramen ovale without touching the base. The passage through the foramen ovale is made manifest by sudden radiating pain in the area of the third branch and by resistance offered by the nerve. X-ray examination of the position of the needle prior to coagulation is imperative. Examination of the eyes is important because changes in vision, in the size of the pupils and in the ocular movements suggest that a change in the position of the needle is required. This may also be necessitated by aspiration of blood or cerebrospinal fluid or by nausea. After these precautionary measures, high frequency electrocoagulation with the alternating current may be performed under evipal sodium anesthesia. Coagulation should be made in four stages of fifteen, twenty, twenty-five and thirty seconds' duration. The intensity of the current is increased during the last stage. Coagulation itself should not be performed under local anesthesia. Residual pains may persist for two or three days. Electrocoagulation may be repeated when pain persists on the fifth or sixth day, as well as in recurrences. The advantage of the method is that the effect of the current is limited to the area immediately next the cannula, thus preventing severe destruction at the base of the skull or extensive bone sequestration in the area of the base and of the upper jaw.

Pathology of Round Ulcer During First Year of Life. H. Mellerowicz. —p. 41.

Sulfonamide Therapy of Typhus and Diphtheria.—Harmsen and Siegler report experiences with sulfonamide therapy in 30 severe toxic cases of diphtheria and in 23 cases of typhus complicated by diphtheria. Intravenous injections of large doses of sulfaethylthiazole (7 to 8 Gm.) were given for two to three days. Rinsing of the mouth and of the throat with a 3 to 5 per cent solution of sulfaethylthiazole was practiced at the same time. Rapid shrinking of false membranes took place and the membranes were cast off within three to four days. Edema of the throat subsided rapidly. Smears became negative within a short time. Sulfaethylthiazole was particularly effective in cases of mixed typhus and diphtheria infection complicated by pneumonia. The mortality rate was reduced from 80 per cent to 30 per cent.

*"Vegetative Insulin Shock" in Treatment of Urticaria. H. Bartelheimer. —p. 286.

Full Diet in Diabetes Mellitus.—Food conditions in Germany prompted Nonnenbruch to suggest that patients with diabetes mellitus should be granted the same rations as normal persons. According to Banse, change in metabolism for the worse resulted from a full diet consisting of unlimited carbohydrates and of normal small rations of fats and proteins with the addition of sugar and sweet marmalade. Results with limited diet consisting of unlimited carbohydrates without the addition of sugar were on the average satisfactory. Of 1,200 patients with diabetes 228 were given a full or limited full diet. Experiments were carried out on 170 men and on 58 women of various age groups as well as on children. The limited full diet was well tolerated by 136 (114 men and 22 women), i. e. 11.3 per cent of the total of 1,200 patients. Insulin was administered simultaneously to 96 patients (82 men and 14 women), whereas 40 (32 men and 8 women) did not require insulin. These 96 patients had "island diabetes"; they did not present symptoms of severe endocrine disturbances of metabolism. Insulin treatment was effective, the blood pressure was normal and there was no tendency either to obesity or to emaciation. The fasting blood sugar values of the 40 patients not on insulin treatment were up to 130 and 140 mg.; there was a mild glycosuria independent of the food, so that the terms diabetes lenissimus and diabetes innocens could be applied to them. The dose of insulin required in cases in which a prolonged limited full diet proved satisfactory was not higher than that of patients on a diabetic diet. Normal carbohydrate tolerance could not be produced in patients with diabetes mellitus by the administration of insulin. On limited full diet the normal work capacity could be maintained and a change of metabolism for the worse could be prevented in only a small portion of men. In all other patients, particularly in women, a sufficient metabolic balance could be maintained only on a diet which took into account the reduced carbohydrate tolerance.

"Vegetative Insulin Shock" in Treatment of Urticaria.—Bartelheimer treated with insulin several hundred cases of acute urticaria. Hypoglycemia characterized by vegetative symptoms can be produced by subcutaneous administration of 30 to 40 units of insulin. The rash subsides promptly with the outbreak of sweat and the occurrence of tremor, fatigue and palpitation. The more pronounced the vegetative symptoms of the insulin shock, the better the effect of the treatment. Intravenous injections of 10 to 16 units of insulin are suggested. Attention to the normal function of the kidneys and the pituitary is important in order to prevent severe hypoglycemia. The risk of circulatory failure has been overestimated, but electrocardiographic examination should be carried out prior to insulin administration in cases of rash following administration of diphtheria or scarlet fever serum. Satisfactory results were obtained with insulin shock treatment in these specific cases. Intravenous administration of the drug is not advisable in these cases and in hypotension. The treatment is likewise effective in chronic urticaria with repeated administration of small doses of insulin once or twice a day.

Book Notices

Foundations of Neuropsychiatry. By Stanley Cobb, A.B., M.D., Bullard Professor of Neuropathology, Harvard Medical School, Boston. Third edition. Cloth. Price, $2.50. Pp. 252, with 13 illustrations. Baltimore: William Wood & Company, 1944.

The popularity and usefulness of Dr. Cobb's book is attested by the fact that it is now in its third edition. It is surprising to note how well the author has performed his task of simplifying and schematizing a complex subject. In doing so he has of course subjected himself to the criticism of eliminating much important material and of being guilty of dogmatic assertions when these are not possible. It is difficult to see how these can be avoided in attempting to present neurology to medical students, and it should be borne in mind that to simplify adequately presupposes a sound knowledge of the subject in question. In this regard the author qualified without question. To follow the opposite extreme would be to make the subject both unpalatable and unintelligible. Despite the pitfalls inherent in his chosen approach to the problem of neuropsychiatry, Dr. Cobb has succeeded admirably in writing a book which does indeed present the essential features of a complex branch of medicine.

It is gratifying to note that although the author has always been a sound advocate of the inseparability of structural and psychogenic processes he has not found it necessary to resort to psychosomatics as a new form of psychiatric thinking. His little volume is testimony to the fact that psychosomatics has always occupied those neuropsychiatrists with a broad vision of their field.

The chapter on special neuropathology would have been more useful if it had been confined to a general discussion of neuropathologic processes such as demyelination and infection. Its consideration of the special diseases is too brief to be really useful. The chapter on psychopathology is subject to the same criticism. It would seem better to have confined the discussion of this problem to general concepts than to have attempted thumbnail sketches of diseases.

There has been added in this edition a new chapter on psychology which discusses briefly such problems as the instincts, intelligence, memory and attention. It is much too brief to cover the subject adequately, but it is useful in that it provides a springboard for further reading and presents a point of view on which further knowledge can be based. This is probably the most important feature of Dr. Cobb's book, that it provides a background and point of view which can be expanded or contracted as the student desires. There can be no hesitation in recommending the book highly not only to medical students but to all those who contemplate choosing neuropsychiatry as their field of choice.

Modern Methods of Amputation. By Edmundo Vasconcelos, Professor, University of São Paulo. With an Introductory Survey of the Development of Amputation by Major Gen. Norman T. Kirk, M. C., Surgeon General, U. S. Army. Fabrikold. Price, $10. Pp. 253, with 238 illustrations. New York: Philosophical Library, Inc., 1945.

This volume contains information valuable to any practitioner who may be faced with a problem of amputation surgery. The general principles of amputation are well stated. The distribution of skin flaps, the handling of muscle and fascia, the treatment of bone, with emphasis on respect for periosteum and the treatment of the nerve trunks, are all clearly and soundly stated in the text. Some of the instruments for and methods of retraction, which are so well illustrated, will however in unskilled hands lead to great stripping of the periosteum. Their hazards are not stressed.

The levels of amputation are cleverly and strikingly illustrated. As stated for the upper extremity, no exception can be taken. As stated for the lower extremity the level of 5 centimeters below the middle of the calf for an ideal below the knee amputation stump is open to question. This is considerably longer than the American prosthesis maker likes to fit and is in an area of the calf which is likely to have poor circulation and ulcerate easily.

The technics for individual amputations are well described, particularly the technic of the Syme-Ollier amputation, in which the author stresses the vulnerability of the blood supply to the flap and its protection by subperiosteal stripping of the os calcis. No other modern treatises on amputations cover well the pitfalls in this valuable procedure.

The paragraphs on interscapulothoracic amputation and disarticulation of the hip are in great detail and effectively illustrated in a manner to make the anatomy clear. Other modern textbooks on amputation leave much to be desired concerning these very major operations, which this volume makes clear.

The extensive description of the various modifications of amputations of the osteoplastic type through the astragalus and os calcis, including an original operation by the author, is interesting and is of value to the expert in amputations. However, the simplicity with which they are presented is likely to lead the average surgeon into procedures which will result unsatisfactorily. The successful selection of patients for these types of procedure and the execution of the operation require considerable experience in bone surgery, and these procedures should not be carried out by even the greatly experienced soft tissue surgeon.

The chapter on prosthesis is an outline and should be more detailed. While the important elements in after-care of the stump, viz. massage, active exercise, elimination of contractures and muscular development, are all mentioned briefly, there is much detail of this important aspect of rehabilitation which could be included and stressed with benefit to both practitioner and patient. No mention is made of the importance of teaching from the beginning proper walking habits, the technic of which is extremely important to the ultimate result of the surgery.

A chapter on the immediate complications of the surgery, viz. shock, hematoma, infection, necrosis of skin flaps and their management, would be a valuable addition toward completeness.

The illustrations are well done and informative and they stress the anatomic aspects of the operative procedures. All however show clearly an unnecessarily extensive undermining of the skin in the subcutaneous plane, which in some instances will result in the complication of necrosis of the skin flaps.

This book is one from which the expert, the practitioner who occasionally does an amputation and the student can all get ideas. It is a valuable addition to the literature on this phase of surgery and should be in every surgical library.

Colloid Chemistry Theoretical and Applied. By Selected International Contributors. Collected and Edited by Jerome Alexander. Volume V: Theory and Methods, Biology and Medicine. Cloth. Price, $20. Pp. 1,256, with illustrations. New York: Reinhold Publishing Corporation, 1944.

This large volume covers the "more recently developed theories, methods and procedures, as well as new topics or newer aspects of old topics" in colloid chemistry. The book is divided into two major portions. It is unfortunate that the second part (Biology and Medicine) could not have been published separately; for the first section will not appeal to the medical profession as a whole.

The first part (Theory and Methods), consisting of twenty-five chapters, includes descriptions and discussions of methods for the analysis of complex molecular structures with the aid of x-rays, the electron microscope (which includes some fine photographs of micro-organisms), high vacuum distillation, polymerization, sonic and ultrasonic waves in colloid chemistry, the cyclotron and some of its uses (especially in biology and medicine), electrophoretic studies of proteins and related substances (with part devoted to the electrophoretic study of blood, hormones, serums and numerous references to its use in other biologic studies). This section, as a whole, is written in a highly technical vein appreciated by the physicist, chemist or engineer but outside the ken of most medical practitioners.

The second portion of the book is also technically presented but obviously within the grasp of the physician. Articles covering the following subjects are presented: proteins; catalysis as a biologic factor; photosynthesis; plant cell membranes; recent advances in starch chemistry; enzymes and the biologic action of vitamins; minerals and vitamins in applied nutrition; mechanism of hormone action; molecular organization of visual processes; chemical pacemakers and physiologic rhythms; colloid chemistry of purified viruses; the gene as a structure of colloidal dimensions; the gene as a chemical unit; colloid chemistry in embryonic development; physical states of protoplasm compatible with life; physical properties of protoplasm; surface-

chemical properties of protoplasmic proteins; physical change of muscle related to activity; capillary circulation; biochemical and physiologic mechanisms in inflammation; modern outlook on blood coagulation; immunology; allergy and anaphylaxis; homeostasis (the maintenance of steady states in the organism); causes and nature of cancer; gerontology; formation of concretions; aero-emphysema and caisson disease; action of war gases; infective aerosols; physical chemistry of lipids, physicochemical mechanisms in neuropsychiatric disorders; psychiatry; changes in the surrounding medium produced by free living cells; physicochemical basis of organic evolution. Each chapter carries an extensive reference list.

These chapters are written by workers who are generally recognized as authorities in their respective fields. Such names as C. A. Elvehjem, Oliver Kamm, W. M. Stanley, Robert Chambers, Otto Meyerhof, William C. Boyd, Carl A. Dragstedt, Walter B. Cannon, Leo Loeb and A. J. Carlson constitute only a partial but representative list of the authors.

In addition to his knowledge and organizational ability, one of the editor's chief assets lies in his capacity to point out the significance of experimental data and present it in the proper perspective relative to the general pattern of biologic science.

The second half of the book is certainly of great value and interest to the physician, for it correlates and integrates physiologic and biochemical actions with the phenomena of living processes. In the various articles the doctor is given an opportunity to reacquaint himself with, or to learn of, new facts and theories on numerous subjects, each presented in relatively few pages.

The Pathology of Internal Diseases. By William Boyd, M.D., LL.D., M.R.C.P., Professor of Pathology and Bacteriology in the University of Toronto, Toronto. Fourth edition. Cloth. Price, $10. Pp. 857, with 374 illustrations. Philadelphia: Lea & Febiger, 1944.

This edition has been brought up to date with particular reference to such subjects of current interest as primary atypical pneumonia, Q fever, blast injury, Meigs's syndrome, dietary cirrhosis of the liver, infective hepatitis, alloxan diabetes, crush nephritis, sulfonamide nephritis, the Rh factor, sarcoidosis and equine encephalomyelitis. The discussion of diseases of the cardiovascular system has been amplified, and various other sections have been rewritten "in part or in whole." Twenty-two new black and white illustrations and four new colored plates have been added. The value of this book rests mainly on its correlation of symptoms with pathologic lesions, thus making pathologic anatomy the keystone of clinical medicine. As the author said in the first edition, this book is meant to be essentially "an illustrated textbook of internal medicine written from the point of view not of diagnosis or of cure but of the mechanisms of disease, its why and its wherefore." Although the book is of particular value to medical students studying special pathology, it should be of equal value to clinicians who wish to keep abreast of advances in clinical medicine. The discussions are necessarily brief, but the author's ability to condense and the excellent illustrations make the reading easy. The book should continue to serve well its original purpose.

An Experiment in Applied Nutrition for Canadian Communities. Summary Report of the Swift Fellowship. By Edna M. Guest, O.B.E., M.D., and Miss Ethel Chapman. Paper. Pp. 192. Toronto: Trustees of the Swift Fellowship, 1944.

This is the report of the work carried on in the year 1942-1943 under a fellowship providing for visits by a home economics nutritionist to local communities of all sections of Canada. In each town conferences were held with all available persons interested in or acquainted with nutritional problems such as public health nurses and doctors, teachers, women's clubs and nutrition committees. Encouragement and advice for planning nutritional improvement was given to individuals and groups. Plans were made for overcoming local food problems. Follow-up reports from the communities are given which show the achievements made as a result of the worker's visit. It was felt that in each case definite benefits were traceable to the personal visits made possible by the fellowship. This served to bridge a gap between the scientific sources of knowledge and its practical application.

Lições de anestesiologia: Curso realizado sob os auspícios da cátedra da Universidade de S. Paulo e da 2.ª região militar. Raul Briquet, editor. Com a colaboração de P. Alves Neto, et al. Boards. Pp. 411, with illustrations. São Paulo: Editora Atlas S. A., 1944

The editor, with nineteen collaborators, has reviewed the literature in connection with the administration of anesthetics and has emphasized methods employed, particularly in the United States. Some of the subjects covered are the evolution of anesthesia and the effects of anesthetics on the central nervous, respiratory, circulatory, digestive and urinary systems. The chemistry and pharmacology of anesthetic agents are discussed, as are preliminary medication, surgical anesthesia for war, inhalation anesthetics and rectal, intravenous, spinal, peridural, local and regional anesthesia. Technical problems of anesthesia and the subject of respiratory obstruction and the postoperative complications are considered in detail. There are chapters on oxygen therapy and on gas anesthesia apparatus. This volume is evidence of great interest in anesthesiology in South America, especially in Brazil and in the University of São Paulo. Anesthesiologists will be impressed with the thorough comprehension of all the commonly used methods of anesthesia that are covered.

Functional Disorders of the Foot: Their Diagnosis and Treatment. By Frank D. Dickson, M.D., F.A.C.S., Associate Professor of Clinical Surgery, Medical School, University of Kansas, Kansas City, and Rex L. Diveley, A.B., M.D., F.A.C.S., Colonel, Medical Corps, Army of the United States. Second edition. Fabrikoid. Price, $5. Pp. 352, with 292 illustrations. Philadelphia, Montreal & London: J. B. Lippincott Company, 1944.

In its second edition this work has undergone much improvement, with additions of chapters especially related to military and industrial phases of foot problems. As the title suggests, the routine foot problems confronting practitioners are resolved to their simplest terms by sound reasoning. Diagnoses are classified and treatment is outlined. Dignity is given to the entire foot problem. The book is recommended to all, especially the military, pediatrician and general practitioner. Numerous photographs and line drawings supplement the text. A well organized bibliography contains many references for supplemental reading.

Uncle Sam Convalescing: A Glimpse into His Hospital Record from 1933-1940. By H. Ameroy Hartwell, M.D. Cloth. Price, $2. Pp. 79, with 6 illustrations. Boston: Bruce Humphries, Inc., 1944

"Uncle Sam Convalescing" is an interesting, original, economic case history and day by day hospital record of the first seven critical years of 1933 to 1940. Free use of charts, physical examination forms and summary sheets enable the reader to trace the rise and fall of pulse rate, blood pressure and general all around condition from the closing of the banks until Hitler and Mussolini began to show uncontrollable maniacal tendencies. Throughout the author deals with national events in the language of medicine which is amusing, surprising and entertaining, particularly in the early pages.

Notable Names in Medicine and Surgery. By Hamilton Bailey, F.R.C.S., Surgeon, Royal Northern Hospital, London, and W. J. Bishop, F.L.A., Sub-Librarian, Royal Society of Medicine, London. Cloth. Price, 15s. Pp. 202, with illustrations. London: H. K. Lewis & Co., Ltd., 1944

Here are almost a hundred brief biographies, with photographs of great names in the history of medicine, particularly eponyms. The descriptions are brief. The great number of illustrations make the book especially living and delightful. Several Americans are included, notably Sims for the speculum, Bigelow for a ligament, McBurney for his point, Welch for his bacillus, Ochsner for his treatment of appendicitis, John B. Murphy for his drip, his sign and his button, Kelly for the proctoscope, and the Mayos for some operations and the scissors.

Alcoholics Are Sick People. By Robert V. Seliger, M.D., in collaboration with Victoria Cranford. Edited by Harold S. Goodwin, B.A. Cloth. Price, $2. Pp. 80. Baltimore: Alcoholism Publications, 1945

This small treatise is one of the best on alcoholism. It is about time that the layman be made to recognize the fact that the abuse of alcohol is a psychiatric disease as well as any other disease and that the patients need treatment by a psychiatrist. The author's book actually does this. It is thoroughly honest and straightforward. It should be in the hands of all medical men and social workers.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

TESTS FOR DRUNKENNESS

To the Editor:—As assistant city physician I am interested to know the best ways to find out when a person is inebriated (drivers) so I can prove it in court. I bought a LaMotte set and had it used twice during the last fifteen days on the urine of intoxicated drivers. I just got my copy of Approved Laboratory Technic by Kolmer and Boerner and to my dismay I read on page 905 that the estimation of the amount of alcohol found in the urine is valueless. Please tell me how can I prove that a person is inebriated without having to anesthetize or kill him? Also please tell me the percentage of alcohol that should be in the urine of the person examined to be called drunk and the percentage in the four stages of acute alcoholism. Jesus Chapa-Badillo, M.D., Laredo, Texas.

ANSWER.—This query is based on the following quotation from Kolmer and Boerner:

It has been fairly well established that the various methods to determine intoxication, such as an estimation of the amount found in the urine or expired air, are valueless, since they are excreted and no longer causing inebriation. (Inebriation depends upon the amount of unoxidized alcohol in the brain.) Hence the ideal method is to determine the amount of alcohol present in the brain tissue. This of course is easy in the cases coming to necropsy but correspondingly difficult in an intoxicated individual. In such cases examination of the spinal fluid is probably of greatest value. For further details the reader must consult the enormous literature which has accumulated.

The assertions in this quotation are so obviously contrary to generally accepted opinions that Kolmer was asked to clarify the situation. He explained that the material under discussion had been written by a collaborator, who had based his opinions largely on the work of Gettler and his associates, and that this material had escaped revision. That Kolmer himself is in complete accord with the investigators who admit the importance of testing all body fluids is evident from quotations from his book Clinical Diagnosis by Laboratory Examinations (D. Appleton-Century Company, 1944):

Ethyl alcohol intoxication may be detected also by tests conducted with the breath and urine. With the latter a concentration of less than 0.1 per cent produces no intoxication; mild intoxication may occur in about 50 per cent of individuals with a concentration of 0.1 to 0.2 per cent; moderate intoxication with 0.2 to 0.3 per cent, and marked intoxication with 0.4 per cent or higher.

These statements are documented with references to the literature, and a more complete discussion of concentrations of ethyl alcohol in the blood in relation to intoxication is given on pages 194 and 195. In 1931 Gettler and Freireich reported a closer relationship between brain alcohol and spinal fluid alcohol than between brain and blood alcohol, and they concluded that brain alcohol and spinal fluid alcohol furnish the only adequate chemical criteria for intoxication. Again in 1944 Gettler, Freireich and Schwartz reported additional information on blood and brain alcohol. They determined the blood-brain alcohol ratio in a series of 28 dogs that had been given alcohol by stomach tube. From their experiments they concluded that the alcohol in the blood and other body fluids varies so greatly from brain alcohol that these fluids are unsuitable for diagnosis of inebriation in man. This work is open to criticism from many standpoints. The method of analysis used accounts for from 83 to 89 per cent of the alcohol present, and yet the authors report their findings to the third decimal place—mathematical precision with insignificant figures. The extreme limits of brain-blood ratios in dogs were used to calculate possible variations in human brain alcohol based on blood alcohol determinations. The dog furnishing one of the extreme blood-brain ratios was killed just seven minutes after the alcohol was administered, the time interval being ridiculously short for medicolegal interpretation. Finally, their mathematical calculations are erroneous, since they inverted their dog brain-blood alcohol ratios when figuring possible brain alcohol variations in man. The importance of blood and spinal fluid alcohol has been adequately summed up by Bogen:

Although Gettler's results, showing a closer relationship of brain alcohol to spinal fluid alcohol than to blood, seem contradicted by Newman and others, the differences between them would rarely lead to a change in diagnosis. On the other hand, there is available abundant data showing a close relation between blood alcohol and behavior.

It is true that chemical examination of the brain tissue would help solve the drunken driving problem by preventing individual repetitions of drunken driving and that spinal fluid alcohol is related to brain alcohol. But it is also true that the alcohol in the blood is responsible for the distribution of alcohol to the brain and all body fluids. Alcohol tends to disperse itself uniformly in the water of the body, so that, after equilibrium has been established, examination of any tissue or body fluid gives information regarding the unoxidized alcohol in the body. The urine, being a filtrate from the blood, is suitable for examination, although the alcohol readings are lower than those of the blood shortly after drinking. This low alcohol reading is to the advantage of the accused. A second specimen of urine taken about half an hour later will give a truer picture of his condition. That the urine is of great value in the practical confirmation of alcoholic influence was shown by Halporn when he was able to predict with remarkable accuracy the percentage of urinary alcohol from the examination of drivers who had been arrested for driving while under the influence of alcohol. Bogen has demonstrated that the alcohol of the spinal fluid and that of the urine are practically identical. This work was confirmed but not published by Heise, who also found in unpublished observations that the occasional discrepancies between blood and urine alcohols as described by Haggard were associated with close approximation of urine and spinal fluid alcohol levels. However, the amounts of alcohol in the urines under these unusual conditions have not been found to be high enough to have medicolegal significance. The value of tests for alcohol in the breath has been established by Harger, Haggard and Jetter. Although there is some disagreement regarding methods of analysis and interpretation of results, it is agreed that the expired air closely reflects the alcohol in the blood. Friedemann has shown that the alcohol in the saliva can be used to predict blood alcohol. That the blood alcohol furnishes an adequate criterion for medicolegal interpretation is generally accepted. The only disagreement comes from Gettler and his disciples. The apparent disagreements regarding the medicolegal interpretations of various levels of alcohol in body fluids arises from the misunderstanding between the expressions "under the influence" and "intoxication." Gettler, for example, finds that all individuals having more than 0.25 per cent alcohol in the brain are intoxicated but that there is a loss of sense of care or aggressiveness in persons who have between 0.10 and 0.25 per cent. Jetter reports "acute intoxication" in 100 per cent of persons having a blood alcohol above 0.45 but is nevertheless in complete agreement with the recommendation of the National Safety Council that a level of the blood above 0.15 per cent should be considered as definite evidence that a person is "under the influence." The National Safety Council's Committee on Tests for Intoxication and the Committee for the Study of Problems of Motor Vehicle Accidents of the American Medical Association have agreed that when the level of alcohol in the blood or its equivalent in other body fluids is below 0.05 per cent the influence by alcohol is doubtful; that most persons are under the influence when the alcohol percentage is between 0.05 and 0.15, but that the physical signs and symptoms should be carefully considered in rendering an opinion of "under the influence." All persons harboring 0.15 per cent or more of alcohol in their bloods are to be considered "under the influence," since they have lost, at least to some extent, some of that clearness of intellect and self control that they would otherwise possess. Laws embodying this interpretation have been passed by Indiana, Maine and New York, and the tests have been admitted as evidence in almost every state of the Union.

It is difficult to define stages of intoxication on the basis of alcohol percentages because of the differences in behavior of individuals. There is, however, a definite pattern, based on the fact that alcohol first of all affects that part of the nervous system which in its evolution was developed last and that, as the alcohol percentage rises, the more primitive parts of the nervous system are involved. When the higher centers are involved, which may occur with as little as 0.02 per cent alcohol in the blood, there is a sense of careless well-being or of bodily and mental comfort. The apparent stimulation arises from loss of inhibitions, associated with some loss of judgment and self-control, and particularly a blunting of the ability for self criticism. There is no obvious intoxication, and the individual in this state has probably not increased his chances for having an accident. A second stage begins with levels of alcohol somewhere between 0.05 and 0.15 per cent. The part of the nervous system which is now being affected extends to the centers concerned with the sensory and skilled motor functions. Hand-eye coordination becomes impaired, speech may be slurred and the individual may feel that he is detached from himself, so that he can observe with amusement or consternation the bodily actions

of his other self. The third stage begins at levels somewhere between 0.10 and 0.40 per cent, when the most primitive functions are disturbed. The intellectual processes of judgment and self criticism are virtually suspended, perception and coordination are impaired, and the individual can respond only to strong appeals to his emotions. However, even in this state he frequently pulls himself together sufficiently to impress onlookers with his sobriety, only to fall into a heavy sleep when the need for self control has apparently passed. Death usually occurs when the blood alcohol exceeds 0.40 per cent.

PREMENSTRUAL PAIN

To the Editor:—A married woman aged 41, without children, complains of severe pain in the lower part of the abdomen and the pelvis radiating to the back. The pain, which is described as being like a severe toothache, comes on each month about five days before menstruation is due. It strikes four or five times a day—more often during night than day—and lasts from five to ten minutes. The attacks are accompanied by the formation of a great deal of gas, but belching or passing gas from the bowel by using an enema does not stop the pain. These attacks have occurred every month for several years and always stop as soon as the menstrual flow starts. The patient had peritonitis in 1925 followed by *the formation of an abscess in the abdomen, which was evacuated.* Otherwise the history is not significant. The patient appears healthy and feels well except when these bouts of pain occur. Examination was essentially without significant findings except that the cervical canal seemed very narrow, but dilation a few days before the pains were due to start had no effect. All sorts of pain relievers, sedatives and hormone preparations have been tried without benefit.

H. W. Byrn, M.D., New Albany, Ind.

ANSWER.—This is indeed a puzzling case. The limitation of the symptoms to the few days before each menstrual flow may perhaps permit the association of this case with the syndrome known as premenstrual tension or premenstrual distress. The name premenstrual tension was given by Frank to a condition which is not uncommon. The symptoms start about a week before menstruation and may consist of headache, emotional instability, irritability and psychic depression. Frequently there occur abdominal distention, nausea and vomiting, increased sex desire, vulvar pruritus and sometimes edema of the vulva. Minor degrees of premenstrual distress are quite common but are accepted by many women without question as a normal feature of menstruation. When the disturbances become extreme, the condition is then assumed to be premenstrual tension. Frank has suggested that this condition is due to an increased concentration of estrogenic substance in the blood stream. Progesterone and testosterone propionate have been recommended as effective remedies. One to 5 mg. of progesterone or 5 to 10 mg. of androgen injected two or three times during the week preceding the anticipated menses has proved beneficial in some of these cases.

The hypothesis has been advanced by Greenhill and Freed (*Endocrinology* **26**:529 [March] 1940) that premenstrual tension is due to the increase in extracellular fluid of the various tissues such as the brain, gastrointestinal tract or skin. This edema gives rise to the symptoms which are typical of this condition. For this reason these investigators have treated their patients with ammonium chloride 0.6 Gm. three or four times daily, together with a sodium chloride free diet, starting at the midperiod and continuing to the beginning of menstruation in an attempt to cause a decrease in extracellular fluid. This therapy has benefited almost all patients who have been treated.

Some of the patients relieved had peculiar, localized edema. Perhaps in this case there is an undue amount of edema and distention of the intestine which produces the patient's symptoms. The attack of peritonitis may or may not be linked up with the patient's symptoms but probably not in view of the lapse of twenty years. Premenstrual intestinal distention is definitely relieved by ammonium chloride, and perhaps therefore the same treatment would help this patient.

DIAGNOSIS OF KERATOTIC LESION OF SKIN

To the Editor:—A man aged 60 has a *cornified patch of skin about the size of a silver dollar on the back of his hand. This has been caused by too many x-ray treatments for an eczematous condition which he had on both hands for several years. What treatment is suggested?*

M.D., Missouri.

ANSWER.—This lesion suggests at once the probability of a low grade squamous cell epithelioma. A biopsy should determine this point. If the lesion is merely hyperkeratotic, the application of an ointment containing 2 parts of 3 to 5 per cent salicylic acid in petrolatum and 1 part of lanolin should be of value. If the lesion has become neoplastic, vigorous fulguration should be used or excision with a skin graft if necessary.

SKIN TESTS IN ALLERGY

To the Editor:—Have there been any extensive studies of the correlation between *skin tests with allergens and other allergic manifestations? Are* there many instances of normal persons whose skin reaction is positive, although clinical manifestations of allergy to the substance showing the *positive skin test are not experienced?*

Perry B. Preston, M.D., Newark, N. J.

ANSWER.—In his presidential address, Dr. Louis Tuft presented to the American Society for the Study of Asthma and Allied Conditions a "Critical Evaluation of Skin Tests in Diagnosis." Much of the early work in this field was reviewed in the presentation.

Positive skin tests without any clinical sensitiveness to correspond are common enough. In 1935 Rackemann and Simon made skin tests by the intracutaneous method on 60 patients chosen at random in the medical wards and found that exactly half of them had positive reactions of varying size to some allergen. Since then, almost each day in a busy clinic, one can demonstrate patients with positive skin reactions who do not have symptoms to go with them. A common example is the patient who has hay fever in August with no trouble at all in June, and yet his skin tests made by the scratch method with pollen extracts in serial dilutions will show reactions to the grasses which may be even greater than the reactions to ragweed. In several cases in which treatment with pollen extract has been highly successful, the skin test made again after an interval of three years has been found still positive even though the patient has had no treatment and no symptoms in the meantime.

Such positive tests can be explained: "false positives" may depend on technic. As Sulzberger puts it, the skin is an "organ of memory." The positive tuberculin test can still be demonstrated in later adult life; and in a patient who in times past was clinically sensitive to a food or dust substance, the sensitiveness of the skin may be demonstrated in later years even though the sensitiveness of other organs has cleared away.

INTOLERANCE TO IRON MEDICATION

To the Editor:—A woman aged 29 breaks out with a skin rash whenever iron is given for a secondary anemia. The skin first has a *macular* eruption of the face, back and trunk, which later on becomes papular and painful. Usually about four or five lesions break out following the administration of iron. She states that, should she continue with the iron, these at times become pustular. I have used ferrous sulfate both with and without enteric coating, ferrous gluconate and calcium gluconate and lactate at the same time. Torantil has also been administered Nothing seems to mitigate the development of this skin reaction.

M.D., Minnesota

ANSWER.—An eruption of the skin is one of the common manifestations of intolerance to iron medication. In these patients it is necessary to depend on food iron after the cause of blood loss has been corrected. The diet should contain whole liver, well cooked meat, strawberries, peaches, apricots, molasses and other foods having easily available iron. If achlorhydria or hypochlorhydria is present, an adequate supplement of hydrochloric acid during the meal is advisable.

VITAL CAPACITY IN PREGNANCY

To the Editor:—*Why is lung air capacity measured in pregnancy?*

L. Edward Giovine, M.D., Woodside, N. Y.

ANSWER.—It is presumed that lung air capacity refers to vital capacity, which normally forms 72 per cent of the total lung volume. The vital capacity is decreased in patients with cardiac decompensation and other conditions in which the volume of the chest is decreased. It is not altered in patients with toxemia of pregnancy. The average vital capacity in normal women is 3,140 cc. ± 40 cc. Thomson and Cohen have followed the same patients throughout pregnancy and conclude that the vital capacity remains within normal limits in normal pregnancy, averaging 100 cc. increase at term and decreasing 138 cc. in the postpartum period. Plass and Oberst noted that the volume of tidal air and the minute volume of respired air increase progressively as term is approached and return to normal during the second week of the puerperium.

VALUE OF HEALTH EXAMINATIONS IN INDUSTRY

A STUDY OF THE COMPARATIVE SICKNESS RECORDS OF A GROUP OF PERIODIC HEALTH EXAMINEES AND A NONEXAMINED CONTROL GROUP

LEVERETT D. BRISTOL, M.D., DR.P.H.
WEST HARTFORD, CONN.

In the fields of preventive and industrial medicine and public health many procedures are difficult, if not impossible, to evaluate with scientific precision. It often is a complicated problem to demonstrate that if so-called preventive measures had not been taken the condition supposedly prevented would have happened. These facts would seem to apply particularly to the routine periodic health examination, frequently referred to as the keystone in sickness prevention and health promotion among individuals or industrial workers.

OBJECT OF STUDY

While there has been ample evidence of occasional abnormal conditions, minor physical impairments and incipient diseases brought to light among individuals, thus making possible their prompt control or remedy, there is as yet no unanimity of opinion or proof that such routine health inventories play a large part or are worth the time, effort and cost involved as a factor in the promotion of group health in general or in the reduction of sickness among industrial workers as a company sponsored activity. Periodic health examinations of workers as a part of an industrial health program fail in important respects as means of prevention if, in addition to helping the individual, they do not contribute to the reduction of employee sickness in general or serve to control absence from work and its resulting costs and inefficiency from the standpoint of management.

This study does not attempt to enumerate the incipient conditions, physical impairments and abnormal health habits found in these periodic health examinations. The chief objective is to show what the correlated history of sickness and absence from work may be over an extended period of time in an examined group as compared with a control group of workers who have not had such periodic health examinations.

GROUPS SELECTED

In order to determine whether or not such periodic health examinations are of value in reducing sickness and lost time from work, a study was made of a group of 100 male workers who had had ten or more voluntary annual physical examinations during fourteen consecutive years in a company medical department. This will be referred to as the examined group. For purposes of comparison, a control or nonexamined group, selected at random so far as their sickness records were concerned, was set up. This control group included 100 male employees of comparable age, years of service, economic status and occupational classification who never had taken advantage of such available examinations during this period of time. The average age of each group was 46 years. Thus the only important variable involved in the two groups was that one had had voluntary annual health examinations while the other had not.

EXAMINATION PROCEDURES

The periodic health examinations of the individuals in the examined group were carried on largely by the same physician, who was recognized as a specialist on such examinations. The form used for several years was that prepared and published by the American Medical Association. The only routine laboratory test included in these examinations was an analysis of the urine. Blood, x-ray and other diagnostic tests were made when required. Following these examinations, the usual advice was given as to the correction of poor health habits, abnormal conditions and impairments found. Such individuals were referred to private physicians for further examinations or for treatment, if indicated as necessary.

SICKNESS RECORDS

The sickness records of these periodic health examinees, as well as of the nonexamined control group, were obtained from data accumulated in connection with the employees' attendance records and the administration of the company's sickness benefit plan. All such records of sickness lasting eight days or over were based on physicians' diagnoses and represented more serious cases. In addition to an analysis of these major cases, this study also includes a comparison of minor, incidental sickness absence of less than eight days' duration in the two groups. The results of this study are shown in the tables.

As noted in table 1, there is practically no difference between the examined and the nonexamined control groups as far as the total incidence or number of cases of major sickness lasting eight days or over is concerned. During fourteen consecutive years of available records, considered as a whole, there were 166 such cases in the examined group as compared with 164 in the control group.

Table 2 shows the total number of cases of sickness in each group, classified according to specific causes. The examined group showed a greater number of cases under five of the specific causes, while the nonexamined

group under four classifications showed the greater number of cases. The nonexamined group had a somewhat larger number of scattering miscellaneous diseases. The number of cases under each cause are not sufficiently large or significantly different to warrant specific conclusions.

TABLE 1.—*Sickness Incidence*

Number of cases lasting eight days or over during fourteen consecutive years in examined and nonexamined groups

Group	Number of Cases
Examined group	166
Nonexamined group (control)	164

TABLE 2.—*Causes of Sickness*

Number of cases by causes lasting eight days or over during fourteen consecutive years in examined and nonexamined groups

Causes of Sickness	Number of Cases: Examined Group	Number of Cases: Nonexamined Group
	44	52
	28	14
	16	24
Diseases of respiratory system (nontuberculous)	16	19
Diseases of nervous system	12	6
Diseases of bones and mastoid	9	1
External causes	7	4
Diseases of kidneys	6	2
Minor epidemic diseases	1	6
All other causes (scattering)	27	36
Total	166	164

Table 3 shows the relative number of cases of major sickness by years in the two groups, divided into two seven year periods. During the first seven years the examined group showed a total of 75 cases of sickness lasting eight days or over, while during the last seven years the total number of cases was 91, or an increase of about 21 per cent. On the other hand, in the nonexamined control group there were 59 cases during the first seven years and 105 cases during the last seven years, or an increase of about 78 per cent. It would appear that the periodic health examinations apparently had had a positive effect during the last seven years in definitely controlling the amount of sickness lasting eight days or over in the examined group as compared with the nonexamined group.

It will be noted from table 4 that on the average there were approximately one and one-half more days of lost time on account of major sickness in the nonexamined as compared with the examined group. This seems to suggest that periodic health examinations at least had some favorable effect in reducing severity and complications.

From table 5 it is found that, comparing the last seven years with the first seven years, there was an increase in the total calendar days absent of about 18 per cent in the examined group and about 63 per cent in the nonexamined control group. Here again the periodic health examinations apparently served to influence favorably the actual duration of major sickness of eight days or over after such examinations had been in operation for several years.

As was the finding in reference to major sickness lasting eight days or over noted in table 1, so also according to table 6, there was no significant variation in the total number of cases, taken as a whole, of short term, incidental sickness between the two groups.

It is suggested from the data in table 7, with reference to the incidence of short term illness by years, that the sickness records of the examined group improved very definitely as the years passed, while the records of the nonexamined control group became less favorable. Comparing the last five years with the first five years, the examined group showed an actual decrease of about 11 per cent in the number of cases of short term sickness, while the nonexamined group showed an increase of about 26 per cent. From this it would seem that the periodic health examinations apparently had a favorable influence in promoting a better sickness record in the examined group after sufficient time had elapsed to permit the periodic health examinations to show their possible cumulative effects in reducing incidental sickness.

As indicated in table 8, there was no material difference between the two groups in the average number of days lost from work on account of incidental or minor illness. In the examined group the average days lost was 1.62 and in the nonexamined group 1.63.

Comparing the last five years of record with the first five, table 9 indicates, with reference to minor incidental illness, that there was an actual decrease of about 3 per cent in total working days absent in the examined group, while at the same time there was an increase of about 47 per cent in the nonexamined group. This is additional evidence that through the possible cumulative favorable effects of periodic health examinations not only the number of cases of short term sickness was controlled, but the duration of such illness in terms of days absent was checked.

COMMENT

On first consideration, it would seem that such a small number as 100 individuals in the examined group and a like number in the nonexamined control group have little comparative statistical significance. It should be emphasized, however, that the examined group represents 100 individuals who had ten or more annual physical examinations, or a total of more than one thousand examinations during fourteen consecutive years, and that their sickness records for this rather extended period of time also were available for detailed study.

TABLE 3.—*Major Sickness by Years*

Number of cases of sickness lasting eight days or over during fourteen consecutive years in examined and nonexamined groups, by years

Year	Examined Group	Nonexamined Group

TABLE 4.—*Duration of Major Sickness*

Average number of days lost per employee on account of sickness lasting eight days or over during fourteen consecutive years in examined and nonexamined groups

Group	Average Days Lost
Examined group	25.95
Nonexamined group	27.46

Such continuous follow-up lends some significance even to these comparatively small groups.

It may be argued by some that comparisons between the two groups are not entirely valid, as the examined group may have been made up of individuals who were particularly and persistently health conscious and careful of their health and who naturally from the outset might be expected to have a superior health record. But this so-called "health conscious" group apparently has no better record with reference to the total incidence and nature of sickness than the nonexamined control group, supposedly not so health conscious. Their sickness records improved only after the periodic health examinations had been taken long enough to show favorable results. It is, of course, impossible to determine what the sickness experience of the examined group might have been if they had not had such periodic health examinations.

TABLE 5.—*Duration of Major Sickness (Calendar Days Absent) by Years in Examined and Nonexamined Groups*

TABLE 6.—*Incidence of Short Term Illness*

Number of cases of short term illness of less than eight days' duration during ten consecutive years in examined and nonexamined groups

Group	Cases of Sickness (Incidental or Short Term)
Examined group	1,247
Nonexamined group	1,262

Some would hold that those who voluntarily seek periodic health examinations instead of being "health conscious" are chiefly the ones who have reason to believe that they have something the matter with them or who tend to be "neurotic" and are anxious to check up on themselves. Even this supposition is somewhat discounted by the finding that the two groups, as far as the total incidence of sickness is concerned, have had practically the same amount and kind during the years studied, with a definite improvement, however, during the last half of the period in the examined group. Strictly speaking, a periodic health examination is not properly so designated unless it is taken on a routine periodic basis of time, regardless of symptoms, signs or suspicions of disease and when the individual is apparently in good health. Incidentally, it should be noted that in the course of this study no instance was found in which the results of periodic health examinations were used as a means for terminating or adversely affecting employment.

SUMMARY AND CONCLUSIONS

A study covering fourteen consecutive years has been made of the concurrent history of sickness and absence from work in a group of 100 male industrial workers who during this time had ten or more voluntary periodic health examinations in a company medical department. For purposes of comparison, a control group of 100 employees who had had no such periodic health examinations was set up and their records of sickness and absence from work during the same fourteen years also were studied. In all respects with reference to sex, age, years of service, economic status and occupational classification the two groups were statistically comparable, with no important variable other than that one group had had periodic health examinations while the other had not.

Tenth	217.0	267.0
Total	989.0	1,240.0
Grand total	2,009.0	2,085.0

The findings and suggestions resulting from this study are as follows:

1. No significant differences between the periodically examined group and the nonexamined control group were found as far as (*a*) the total incidence and (*b*) specific causes of illness during a period of fourteen years are concerned. However, in studying the records of sickness (*c*) by years there is positive evidence that the sickness incidence of the examined group as compared with the nonexamined group improved materially

as the years advanced, resulting apparently from the cumulative favorable influence of the periodic examinations.

2. In considering the total number of days absent on account of sickness, it was found in analyzing the data by years that the periodic health examinations also had an apparent influence in checking the duration of both major and minor illness, particularly as the years advanced.

3. As a case finding agency (*a*) to bring to light and control occasional early cases of tuberculosis, diabetes, occupational disorders and other incipient diseases and (*b*) to discover certain major or minor physical impairments or defects of the heart, eyes, tonsils, teeth and other parts of the body, the periodic health examination always has been considered of inestimable value to the individual and to the general public health. To this also may be added, as a result of this study, the value of the voluntary periodic health examination even from the standpoint of industrial management in the possible control of operating and financial losses due to sickness absence among the workers.

4. For individuals, in having voluntary periodic health examinations, and for industrial management, in providing facilities for such examinations in company sponsored health maintenance programs, the most important requirement is that of persistence, since the ultimate values are somewhat hidden and slow in appearing.

46 Riggs Avenue.

THE ATTITUDE OF INDUSTRY TOWARD X-RAY EXAMINATIONS OF THE CHEST

C. D. SELBY, M.D.
DETROIT

Collectively, industry has no defined attitude on the use of x-rays as an aid in diagnosing diseases of the thoracic organs in employees and applicants for employment. Certain committees of the National Association of Manufacturers and the United States Chamber of Commerce favor the procedure and are promoting it, but they cannot be said to represent industry's attitude, although they do indicate the trend of industry's thinking.

Generally, the attitude of an individual plant in this matter is determined, or at least is influenced, by the position taken by the management's medical adviser, who might be the doctor in charge of the plant medical department, the neighboring physician who treats the injured employees, the manager's own personal physician or a close medical friend. Except for the differences in cost, the management's attitude on the purchase of x-ray equipment is about the same as it is on blood pressure outfits, electrocardiographs and other diagnostic equipment. Usually the manager looks to the medical department, if he has one, for results in the form of health protection for the employees which cannot readily be valued and, as long as the doctor in charge retains the manager's confidence, decisions of this character are in accordance with his judgment. The attitude of industry can be said to be largely that of physicians in industrial and general practice. Industry is prepared to protect the workers against occupational diseases of a pulmonary nature and those arising out of nonoccupational causes which might be aggravated by the conditions of employment, of which the pneumonoconioses and pulmonary tuberculosis are respectively well known examples. Through industrial hygiene engineering methods industry has endeavored with considerable success to control these. Nevertheless, in the absence of specific immunizing agents, industry recognizes the value of early diagnoses in these important diseases, and experience confirms the effectiveness and practicability of x-rays of the chest as a means toward that end.

In relation to jobs associated with certain forms of dust, there is usually no question as to management's attitude. On the other hand, there may be some question on the use of x-rays for purely diagnostic purposes in the nonoccupational diseases. However; management's interest has been aroused by some spectacular experiences occurring here and there, particularly in regard to pulmonary tuberculosis.

Equipment had been installed in the medical department of a plant employing 10,000 people, and the medical director invited the top management group to inspect it. From a mechanical standpoint they were interested and, observing this, the doctor volunteered a demonstration. An important official stepped forward, and when the quickly processed film was placed on the viewing box it showed an apical lesion. In this case a key man was involved and the disability, though fortunately temporary, came at a difficult time and it was somewhat staggering to the organization. Such experiences are not wholly uncommon, for management is just as susceptible to pulmonary tuberculosis as hourly rated workers and perhaps more so under present conditions. When experiences like this occur they are impressively capable of arousing management's interest.

There is another reason for management's interest, and it is much more common than skeptics admit. For lack of a better expression it can be called the humanitarian interest. It does exist, and instances have occurred in which it has seemed to have received priority. The local tuberculosis society of an Eastern industrial city was ineffectually endeavoring to promote chest surveys in local plants. The manager of the largest was approached with an appeal to lead off with a survey in the hope that others would follow his example. Despite the fact that equipment was on order for an x-ray laboratory in his own plant, this manager granted permission, incidentally at a cost of over $2,000, solely to forward what he considered to be a commendable effort. As a sequel several active cases were found, one of which was in the management group.

An equally good example was in a plant of 7,000, about half of the employees being women. On request of the medical director excellent x-ray equipment had been installed for chest work. Wishing to make its use voluntary, the doctor invited a young woman acquaintance to be the first, expecting that she would spread a favorable word through the plant. As she had considerable local athletic fame the result was unanticipated and startling, for she was found to have a minimal-apical lesion. She accepted the shock sensibly and asked the doctor to call in her sister, likewise employed in the plant. Her sister also had an early lesion. Subsequent investigation by the local health department traced the contact to the father of the girls. These cases attracted a great deal of attention, as both

Read before the Section on Radiology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

of the young women were widely known and popular. Needless to say, volunteers quickly established the x-ray procedure. But that is not the point. In talking about the experience later on, which the manager often did, he expressed great satisfaction in the fact that he had made it possible, by purchase of the equipment, for these employees to have the benefit of an early diagnosis and consequently early treatment, with good prospects for recovery.

Improvements in portable equipment and photofluorographic units have popularized mass case finding surveys. While management usually follows the recommendations of the medical profession with respect to these, instances have occurred in which the advice and cooperation of the plant physician have not been sought. Needless to say, surveys are not wholly effective unless the findings are followed up with good medical procedures. There must be complete accord among the patients, the medical profession, the sanatoriums and the public health authorities, with the plant physician performing the functions of a coordinator.

Surveys serve the purpose of case finding, and to that extent they are useful; but, if size permits, in-the-plant x-ray facilities, with suitable arrangements for roentgenographic consultations, are much more desirable for the permanent control of the respiratory diseases in industry. For this reason further interpretations of industry's attitude will be limited to considerations with regard to the operation of permanent plant x-ray installations.

TABLE 1.—*Conditions Disclosed by 6,505 Chest Films*

Active cases of pulmonary tuberculosis:	
Employees disengaged from employment and referred to their physicians for treatment	15
Cases of questionable activity:	
Employees remained at work under medical supervision	6
Arrested cases:	
Employees also remained at work under medical supervision	34

At this point examples of industry's experience are appropriate. With due consideration to the prevalence of tuberculosis in various geographic areas the following may be regarded as fairly representative:

A plant engaged chiefly in the fabrication of military vehicles and airplane parts, located in the Great Lakes region, has a plant population of about 6,000, one third of whom are women. An analysis of 6,505 chest films gave the results presented in table 1.

All original exposures were on 35 mm. films. Confirmatory 14 by 17 films were taken in 357 cases, of which 74 required follow-up films. In addition to the findings in tuberculosis the conditions listed in table 2 were observed.

A plant located in southern Michigan which manufactures small parts for a great variety of war material has been offering x-rays of the chest as a regular feature of preemployment and health examinations for the past six years. In that period 47,424 chest exposures were made. The average plant population is 16,000. The findings are given in table 3.

In establishing chest diagnostic service, industry desires good relationships with all of the parties who are concerned. These parties are the employees, the medical profession, radiologists, official public health agencies and voluntary health organizations.

THE EMPLOYEES

Diagnostic chest service can be mutually beneficial to management and the employees, but for obvious reasons the employees are primarily the most concerned and the success of the service depends on their willingness to go along with the program. Measures for obtaining their cooperation need not be discussed; it suffices to say that the employees must be convinced of the justice of all medical decisions affecting them and their employment. As a feature of preplacement examinations for selective placement, diagnostic chest service can be obligatory; for health maintenance it may be voluntary. If the chest work is regarded as a regular feature of all examinations, as are other diagnostic aids, it is accepted without question as long as the employees have faith in the integrity of the physician in charge of the plant medical department. With respect to the employees, industry's attitude is characterized by a desire to obtain acceptance of a service which can be and should be mutually beneficial to both management and the employees.

THE MEDICAL PROFESSION

Industry does not ordinarily furnish treatment for pulmonary tuberculosis or any other of the conditions that are brought to light by case finding programs unless, of course, they are the results of employment. It is, however, a distinct advantage to the patients if the relationships between their personal physicians and the industrial physicians are those of good mutual understanding. With special reference to pulmonary tuberculosis, these relationships can advantageously be extended to include studies of the places of employment by the attending physicians and on-the-job conferences with the plant doctors. This applies particularly when

TABLE 3.—*Conditions Found Over Six Years in a Plant Employing 16,000*

the patients are thought to be ready for reemployment to safeguard them on their jobs and to plan health maintenance procedures for them, such as how often and how extensively they should be periodically examined. With respect to the medical profession, industry's attitude is characterized by a desire for good mutual relationships between the plant physicians and the attending physicians. The former are expected to take the initiative in effecting these good relationships.

THE RADIOLOGISTS

In industry the diagnoses of pulmonary tuberculosis and other lesions of the thoracic organs are usually based on interpretations of the films and are necessarily tentative. No such diagnoses are complete until substantiated by clinical observation, which is the function of the patients' own physicians and their consultants. Nevertheless, as considerable dependence is placed on the x-ray films, their interpretations should be supported by x-ray knowledge and experience. Hence the radiologists have an important role in the operation of industrial x-ray laboratories. In this respect their relationships can be made to involve responsibilities as follows:

(1) Responsibility for the x-ray technic and the reading of all films, or

(2) Responsibility for the reading of films only, or

(3) Responsibility limited to the reading of films which are not obviously negative.

The first category is the most desirable, with the consultant giving part time service to the plant, but it is not always the most practical. Usually, as plant medical personnel gain experience the consulting radiologists are content to leave routines to them, reserving for themselves the reading of questionable films, and experience has proved that this arrangement is effectual and workable.

With respect to the radiologists, industry's attitude is influenced by that of the medical directors of the plants, who are permitted to make their own arrangements with the radiologists.

THE PUBLIC HEALTH AUTHORITIES

When industrial diagnostic studies of the chest disclose pulmonary tuberculosis, it is essential that the public health authorities be notified. Usually they follow up contacts and perform the other public health functions essential in such cases. Varying in different localities, these need not be discussed here. It is enough to say that industry's attitude in relation to the public health authorities is characterized by a desire for complete cooperation. Just what form the cooperation should take is not always clearly defined, however, and there is often doubt as to whether the plant physician should notify the department or the family doctor. Usually the plant physician does so if the family doctor does not.

THE VOLUNTARY ORGANIZATIONS

Local tuberculosis and public health societies are frequently quite active and influential. One or more plant managers and other industrial officials may be on their boards of directors, in fact often are, and with such support these organizations are likely to influence the whole local situation, including the attitude of industry. Their principal functions are to promote case findings in tuberculosis, better care of patients and their occupational rehabilitation. In these activities industry generally wishes to cooperate as far as is practical.

In conclusion it can be said that industry has no well defined attitude toward x-ray examinations of the chest, that its position with respect to this matter is influenced by the opinions of physicians who are accustomed to advise with management on medical affairs, and that industry's attitude is therefore in reality the attitude of the medical profession.

In making x-ray chest service available to the employees, industry wishes the relationships which necessarily result from case finding to be professionally ethical, suitable to the best interests of the employees and in conformance with local public health regulations and practices.

3044 West Grand Boulevard.

ABSTRACT OF DISCUSSION

Colonel A. J. Lanza, M. C., A. U. S.: There is no definite attitude on the part of industry toward x-rays and x-ray work, but there is no doubt that x-rays are becoming widely accepted as a necessity in well organized industrial organizations. We see a rather wide demand for x-ray work in industrial plants, and we are receiving a constantly increasing demand for x-ray installations in the plants over which we have jurisdiction. In their industrial application they have two distinct types of use: the first and obvious one is in the preplacement examination; and while it is true that their use was initiated in those types of industries in which a pulmonary hazard is involved, they are now coming into use for preemployment examinations in all types of industry. The second important use is in their public health aspect, in the industrial approach to tuberculosis case finding. Governmental agencies, state agencies, health departments, county medical societies have all initiated x-ray surveys in industry for the purpose of tuberculosis case finding; also we have at least two commercial agencies which are pushing this type of work. I have had no contact with the commercial agency type of survey, but it involves certain features or phases that need to be safeguarded. It is for that reason that, as Dr. Selby mentioned, the Council on Industrial Health felt it was highly important, both in the interest of the individual and in the interest of the medical profession, to make certain that whatever agency does mass surveys of tuberculosis in industrial organizations, it should conform to a certain minimum standard of ethical practice, without which the whole business would degenerate into a purely commercial venture for profit. Our object has been to confine tuberculosis surveys and x-ray work in industry to medical lines, through a medical approach, and to guarantee (as far as that can be done) that the interpretation of x-ray films be limited to those who are capable of interpreting them. Any one who has been through the early days of x-ray work in its industrial aspects has seen all the headaches and confusion which have resulted from the interpretation of x-ray films by those who are not qualified. I hope that this day has now passed and that the cooperation of the Section on Radiology and of the American College of Radiology with our Council will insure that only the highest standard of performance will be found in our industrial work.

Robert Willan.—Skin diseases were the subject of treatises by Daniel Turner (1667-1740), Joseph Pleuck (1732-1807) and Antoine Charles Larry (1726-1783), but the first systematic and scientific classification was that of Robert Willan (1757-1812) of London, whose On Cutaneous Diseases appeared in 1808. "His greatest feat," according to Dr. William Allen Pusey in his History of Dermatology, "was his grouping of a great number of various forms of dermatitis under the generalization eczema."—Clendening, Logan: Source Book of Medical History, New York, Paul B. Hoeber, Inc., 1942.

ENLISTED MEN DISCHARGED FROM THE ARMY BECAUSE OF PSYCHONEUROSES

FOLLOW-UP STUDY

LIEUTENANT COLONEL NORMAN Q. BRILL
MEDICAL CORPS, ARMY OF THE UNITED STATES
MILDRED C. TATE
Psychiatric Social Worker, American National Red Cross
AND
COLONEL WILLIAM C. MENNINGER
MEDICAL CORPS, ARMY OF THE UNITED STATES

This follow-up study of enlisted men who were discharged from the Army because of psychoneuroses was undertaken by the Office of the Surgeon General in July 1944 in order to obtain more reliable data than had previously been available concerning the adjustment of these dischargees to civilian life. Information concerning their health as it related to their employment and employability was especially desired.

METHOD

A random selection of men discharged from the Army during the eight month period between May 1, 1943 and Jan. 1, 1944 was made on the basis of serial numbers. All of the men had been out of the service at least six months. Approximately 7,000 names were selected. Basic data used in this study were obtained from the Medical Statistics Division of the Surgeon General's Office and from the Demobilized Records Branch of the Adjutant General's Office. In only 5,937 cases was sufficient information available to warrant inclusion in the study.

A questionnaire to be mailed was drawn up with the assistance of the Morale Services Division. In order to determine whether or not the presence of an individual's name on the questionnaire would in any way influence the validity of his replies, a preliminary sampling of 500 was undertaken. In half of these the individual's name appeared on the questionnaire and in the other half no identification was included. In the latter group, in order to determine whether anonymity was preferred, a note was added stating that it was not necessary to sign one's name.

Assurance was given that replies would remain confidential and that the information would not be transmitted to any other government agency or be used in the veteran's further relations with the Army. It was realized from the start that the replies would represent subjective impressions, perhaps colored by many motives, and that they would not be completely objective. However, it was believed to be important to determine at least what the veterans would say about themselves, recognizing limitations in the reliability of responses obtained in this manner.

From the Neuropsychiatry Consultants Division, Office of the Surgeon General, War Department, Washington, D. C.

Capt. E. A. Lew, Capt. John S. Benz, Mr. Karl Benson and Mrs. Marie D. Wann of the Medical Statistics Division, Office of the Surgeon General, assisted in the collection of basic data and in the tabulation of the results. Lieut. Col. Jonathan D. Hawkins and Miss Melva M. Doyle of the Demobilized Personnel Records Branch, Office of the Adjutant General, assisted in the collection of basic data. Major F. D. Williams, Capt. Daniel F. Connell and Miss Shirley Star of the Research Branch, Information and Education Division, Army Service Forces Headquarters, assisted in the preparation and pretesting of the questionnaire and in the analyses of the data. Major H. E. Johnston, Director of the Office Service Division, Office of the Surgeon General, assisted in the preparation of the report. Miss Tessie Berkman of the American Red Cross assisted in obtaining the personal follow-up reports. Mrs. Jean Fritzsching of the Neuropsychiatry Consultants Division, Office of the Surgeon General, assisted in the preparation of the report. Without the help and advice of these persons and of the American Red Cross, this study would not have been possible.

Replies to this pretesting showed that approximately one half of those who were given the opportunity to remain anonymous chose to identify themselves and that there was no qualitative or quantitative difference in the replies from the main group as compared with the anonymous group.

In all, 5,937 questionnaires with the individual's name on them were mailed to enlisted men discharged from the Army on certificates of disability with the diagnosis of psychoneurosis, and 4,178 (over 70 per cent) replies were received.

Since it was possible that the 30 per cent who did not reply might differ from the others with respect to their health and employment and therefore affect the reliability of the findings, a personal follow-up on a sampling of 200 of this group was undertaken with the assistance of the Home Service of the American Red Cross. Replies obtained in this fashion were essentially the same as those in the large group.

BASIC DATA FROM GROUP STUDIED

Age.—As compared with the age distribution for the entire army, men discharged from the service are an older than average group; 59.9 per cent were 25 years of age or older on entering the military service as compared with a corresponding figure of 46.6 per cent for the entire army.

TABLE 1.—*Age Distribution* of Men Discharged from Army for Psychoneuroses as Compared with Total Army*

Ages (in Years)	NP Discharges, per Cent	Total Army, per Cent
Under 20	7.9	11.5
20-24	32.6	41.9
25-29	25.7	25.5
30-34	20.6	13.5
35 and over	13.2	7.6
Total	100.0	100.0

* For this and subsequent tables the "unknown group" for which data were inadequate was assumed to be distributed in the same proportion as those for which data were obtained.

TABLE 2.—*Marital Status of Men Discharged from Army for Psychoneuroses as Compared with Total Army*

Marital Status	NP Discharges, per Cent	Total Army, per Cent
Single	63.4	59.9
Married	31.2	38.0
Separated	0.5	0.5
Divorced	2.5	1.4
Widowed	2.4	0.2
Total	100.0	100.0

Marital Status.—There was no pronounced difference in the marital status of the follow-up group as compared with the figures for the total army.

Education.—Figures representing educational achievement indicate a lower level for the group studied than the average for the total army. This difference could not be accounted for on the basis of age alone.

Army Grade.—Of those discharged from the service because of psychoneurosis, 70.2 per cent were in the grade of private, as compared with 40.2 per cent, the corresponding figure for the entire army.

Diagnosis.—Almost 75 per cent of the group had been diagnosed anxiety state, conversion hysteria, or mixed type of psychoneurosis. The other types were relatively infrequent.

Incidence of Disciplinary Problems.—Of men included in the psychoneurotic sample 92.4 per cent had no record of trial by court martial; 5.6 per cent had been tried once, and 1.3 per cent twice. Less than 1 per cent had been tried three or more times.

Comment.—As compared with the overall Army averages, the individual discharged because of a psychoneurotic disorder is apt to be older, to have less education and to have made less progress in the Army. There is little to suggest that he has been a disciplinary problem. Anxiety states and hysterical disorders were the most common types of psychoneurosis encountered.

TABLE 3.—*Education of Men Discharged from Army for Psychoneuroses as Compared with Total Army*

Education	NP Discharges, per Cent	Total Army, per Cent
Elementary school, grades 1 to 8	43.4	30.9
High school, 1 to 4 years	45.1	53.2
College, including postgraduate work, 1 year or more	11.5	15.9
Total	100.0	100.0

TABLE 4.—*Grade of Men Discharged from Army for Psychoneuroses, as Compared with Total Army*

Grade	NP Discharges, per Cent	Total Army, per Cent
Private (including aviation cadets)	70.2	40.2
Private, first class	13.9	21.0
Corporal (including T/5)	9.0	18.3
Sergeant (all grades)	6.9	20.5
Total	100.0	100.0

FINDINGS OF FOLLOW-UP

Health.—Health Before Induction: It was found that 48.4 per cent considered themselves to be in good health before induction, 42.8 per cent considered themselves to be in fair health before induction and 8.8 per cent considered themselves to be in poor health before induction.

Present Health: Of those who had considered themselves to be in good health before induction 93 per cent state that their health has deteriorated to fair or poor. Of those who had considered themselves to be in fair health before induction 42.5 per cent state that their health is now poor, while 1.6 per cent now consider themselves to be in good health. Of those who had considered themselves to be in poor health before induction 80.7 per cent still describe their health as poor, while 19.3 per cent report improvement in their health status.

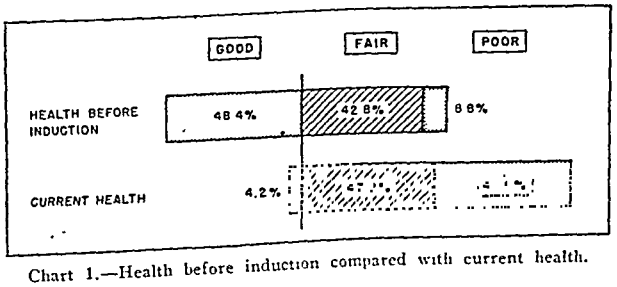

Chart 1.—Health before induction compared with current health.

In reply to the direct question "Is your health the same, better or worse than just before you entered the Army" 72.2 per cent of the entire group reported some deterioration in their health as a result of army service, 25.7 per cent described no change and 2.1 per cent reported that their health at present was better than it had been prior to entering the service.

Chart 2 illustrates that those who considered their health "good" or "fair" at induction reported deterioration in their health more often than those whose pre-army health was described as poor. It shows that men who considered themselves to be in poor health before Army service felt that they had to a much greater extent maintained their health status (52.2 per cent) or improved (6.6 per cent) than those in the "good" and "fair" groups.

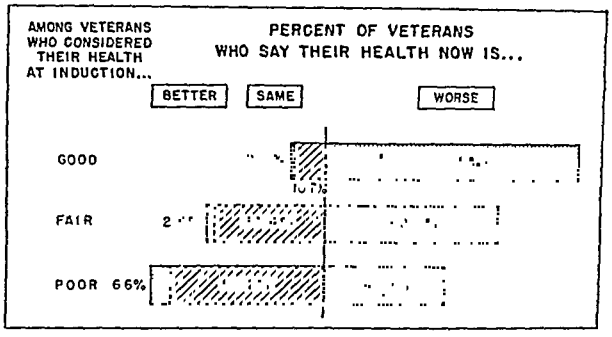

Chart 2.—Health before induction compared with current health.

HEALTH STATUS SINCE DISCHARGE FROM THE ARMY

It was found that 62.3 per cent considered their health to be the same now as their health was at discharge from the Army; 16.5 per cent believe their health has improved and 21.2 per cent believe their present health to be worse than it was at discharge. The greatest change in health status, therefore, seemed to have occurred during Army service rather than following discharge.

It was observed that there was a much greater tendency for the dischargees to look on their illnesses

TABLE 5.—*Diagnosis of Men Discharged from Army for Psychoneuroses* *

Diagnosis	Per Cent
Psychoneurosis, mixed	26.6
Psychoneurosis, anxiety states	21.6
Psychoneurosis, conversion hysteria	20.8
Psychoneurosis, hypochrondriasis	7.0
Neurasthenia	6.1
Psychoneurosis, anxiety hysteria	2.9
Psychoneurosis, reactive depression	1.2
Psychoneurosis, neurosis (somatic)	1.0
Psychoneurosis, obsessive-compulsive states	0.6
Neurocirculatory asthenia	0.5
Psychoneurosis, unclassified	8.7
Total	100.0

* Not uncommonly a mild organic defect was associated with the psychoneurotic disorder and was listed as an additional cause for discharge.

TABLE 6.—*Frequency of Courts Martial Among Men Discharged from Army for Psychoneurosis*

Recorded Courts Martial	Per Cent
None	92.4
One	5.6
Two	1.3
Three or more	0.7
Total	100.0

as physical disorders than as nervous or psychologic disorders.

There was a tendency in those who considered their current health better than it was before induction to believe that their health had improved since discharge. Those who considered their current health the same as it was before induction generally believed their health to have remained unchanged since discharge. It was only in the group who reported their current health as worse than it was at induction that this trend is not apparent. Almost one fourth of these men believe themselves to be worse than they were at discharge. The meaning of this beyond the suggestion of a kind of stability in thinking of one's health in retrospect is not clear.

LENGTH OF SERVICE IN RELATION TO SUBJECTIVE EVALUATION OF HEALTH

In general, the longer a man had been in the service prior to his discharge, the greater was the tendency to report deterioration in health.

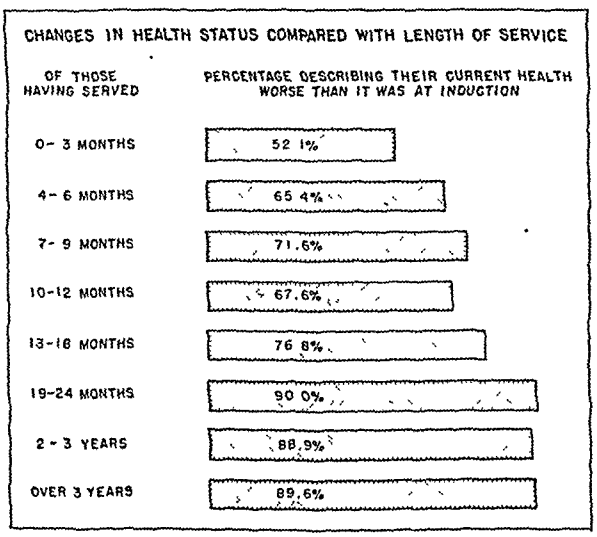

Chart 3.—Changes in status of health compared with length of service.

PLACE OF SERVICE IN RELATION TO SUBJECTIVE EVALUATION OF CURRENT HEALTH

Since length of service of the discharged psychoneurotic individual seems to have a direct relationship to his evaluation of his health status, the relationship between current health and place of service was examined. Proportionately more men who served overseas considered their health poor in comparison with those men who had only domestic service.

Of the total group, 13.7 per cent had overseas service. Of these, 91.9 per cent feel that their current health is worse than it was at induction, whereas only 69.1 per cent of the "domestic service only" men describe their current health as being worse than their health before induction. Only 7.6 per cent of the men who had seen overseas duty believe their health to have remained unchanged, as contrasted with 28.7 per cent of those whose service was domestic. This is illustrated graphically in chart 4.

However, in comparing the men's evaluation of their present health there is not as much difference between the overseas group and those whose service was confined to the continental limits of the United States. One possible explanation for this is that the men who were sent overseas were probably a healthier group.

MEDICAL CARE AND HOSPITALIZATION

Of the entire group 15.3 per cent had been seeing doctors "fairly often" prior to entering the service, 37.9 per cent "seldom" and 46.8 per cent "not at all."

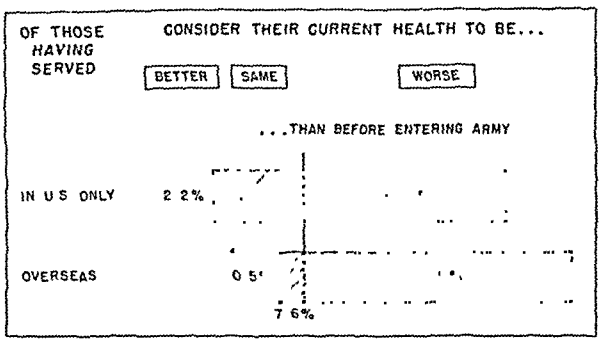

Chart 4.—Relationship of place of service to evaluation of current health and preinduction health.

Since discharge from the Army, 75 per cent of the entire group have consulted a physician one or more times, generally (83 per cent) for the same medical conditions for which they were discharged. In the other instances, physicians were consulted for routine physical examinations, accidents, surgery and complaints unrelated to their previous trouble.

TABLE 7.—*Time Between Discharge from Army and First Hospitalization*

Length of Time Between Discharge and Hospitalization	Frequency
Less than one month	70
One month	83
Two months	75
Three months	65
Four months	70
Five months	53
Six months	69
Seven months	41
Eight months	37
Nine months or more	58
Total	611

Median 3.2 months

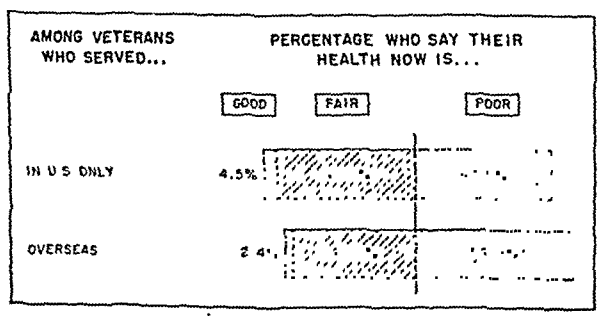

Chart 5.—Place of service in relation to evaluation of current health.

The figures for hospitalization since discharge in part confirm the apparently increased need for medical care. Six hundred and eleven, or 14.6 per cent of the entire group, were hospitalized at least once after leaving the Army. The vast majority (70 per cent) of these were hospitalized only once; 4.7 per cent had four to nine admissions. In some instances, however,

hospitalization merely involved remaining over night for tests.

The length of time elapsing between discharge from the Army and first hospitalization is indicated in table 7.

EMPLOYMENT

Employment at Present as Compared with Employment Before Induction.—While most of the men who have been discharged from the service because of psychoneuroses are working, the incidence of unemployment has increased appreciably. This is particularly significant in view of the current manpower shortage.

TABLE 8.—*Preinduction and Present Occupations*

	Pre-induction	Since Discharge	
Employed	93.7%	85.9%	{ 72%-full time. 28% part time
Unemployed	3.8%	13.1%	
Students	2.5%	1.0%*	
Total	100.0%	100.0%	

* Before the G. I. bill of rights was enacted.

ing the service. The majority of those who were unemployed prior to service are now working. The composition of the present employed and unemployed groups as compared with their preinduction status is presented in table 11.

REASONS FOR REPORTED CURRENT UNEMPLOYMENT

The veterans reporting current unemployment gave a variety of reasons for their failure to work. The majority (71 per cent) gave poor health as the reason and this was usually described as physical. The psychogenic nature of their disorders was apparently not recognized. In 29 per cent unemployment was attributed to factors other than health, such as "shop closed down temporarily" or "no work in my line."

HEALTH AS A FACTOR IN NOT WORKING FULL TIME

A majority of those who were not working attributed their unemployment to poor health, and a considerable percentage of those who were working part time attributed the limitation of their employment to health reasons. Even in the group which was employed full time, however, an appreciable number (18 per cent) reported the need to take some time off from work because of impaired health.

Total remaining within same occupational category: 1,721 or 41%.

PREINDUCTION OCCUPATION COMPARED WITH PRESENT OCCUPATION

Arbitrary categories of employment were set up in order to study the occupational stability of the men discharged. The most pronounced trend was away from the laborer and farmer groups in the direction of operative [1] and clerical groups. Even if the unemployed returned to their preinduction occupations, the post-discharge occupational shift would still be apparent.

The significant reduction in the number of service workers was to be expected because higher paying jobs with better working conditions are available. The categories of business owners and managers, and professional and semiprofessional remain practically unchanged. Of the total group only 1,721, or 41 per cent, returned to the same kind of job after separation from the Army (tables 9 and 10).

THE UNEMPLOYED

The present group of unemployed is made up for the most part of those who were employed prior to enter-

1. This category as defined by Selective Service and the War Department includes workers, usually in industrial plants, who can be hired and taught their tasks in a relatively short time. Their tasks usually are the operation of various types of automatic machines.

TABLE 10.—*Preinduction Occupation Compared with Present Occupation Expressed in Percentages to Show Occupational Changes*

	Preinduction Occupation	Present Occupation
Operatives	31.4	31.6
Laborers	15.7	8.7
Farmers and farm laborers	12.4	8.5
Craftsmen	12.2	11.7
Clerical	7.7	9.7
Salesmen	4.0	3.9
Service workers	3.8	2.3
Business owners and managers	3.6	3.6
Professional and semiprofessional	2.9	2.9
Students	2.5	1.0
Unemployed	3.8	13.1
Total	100.0	100.0

SOURCE OF HELP IN FINDING EMPLOYMENT

Thirty-three per cent of the men returned to their old jobs, 41.6 per cent found new jobs without help and 6.1 per cent were helped by friends and relatives,

9.9 per cent reported assistance from federal agencies, and 1.8 per cent received assistance from sources such as voluntary community groups, unions and fraternal organizations.

ATTITUDE OF PROSPECTIVE EMPLOYERS AS REPORTED BY VETERANS

Of those veterans currently employed, 73.5 per cent experienced no difficulty in getting jobs despite the fact that they had received medical discharges. In this same employed group 22.7 per cent felt that prospective employers showed some hesitancy in considering them for jobs. The largest single reason given was failure

TABLE 11.—*Present Status*

Status before induction	Employed *	Unemployed
Employed *	84%	12%
Unemployed	3%	1%

* Includes those attending school.

TABLE 12.—*Source of Help in Finding Employment*

Source of Help		Per Cent
Returned to old job		33.0
Secured new job		60.0
No help	41.6	
USES	8.6	
Veterans Administration	0.6	
Selective Service	0.7	
American Red Cross	0.6	
Friends or relatives	6.1	
All other	1.8	
Unemployed		7.0*
Total		100.0

* This figure differs from the figure of 13.1 per cent reporting current unemployment. While 93 per cent of the entire group have worked at one time or another since discharge, only 85.5 per cent are now working.

TABLE 13.—*Attitudes of Prospective Employers*

Attitude of Prospective Employers	Employed per Cent		Unemployed per Cent	
Employers showed no reluctance to hire		73.5		59.7
Employers reluctant to hire		22.7		32.5
Failed to pass physical examination	12.4		16.2	
Poor physical risk for industrial insurance	2.7		4.6	
Too "nervous"	2.3		4.4	
Uninterested because of medical discharge	2.9		3.6	
Limitations of work a factor	0.5		0.7

No data		3.8		7.8
Total		100.0		100.0

to pass the physical examination, which some veterans thought was made particularly rigid in order to exclude them. Other reasons for which they were refused employment included "poor physical risk for industrial insurance," "too nervous," "disinterest (on part of employer) because of medical discharge" and "limitations of working capacity."

Of those veterans currently unemployed, 59.7 per cent believed that prospective employers showed no reluctance to hire them because of their medical discharges, while 32.5 per cent did feel that prospective employers showed some hesitancy in considering them for jobs because of their medical discharges. This is a larger percentage than appears in the employed group. In 16.2 per cent failure to pass the physical examination was the reason given for not being hired.

COMMENT

The results of the follow-up study indicate that men discharged from the Army because of psychoneurosis differ significantly from the Army average with regard to age, education and Army grade.

In general, those discharged from the Army with a diagnosis of psychoneurosis consider their health to have been adversely affected by their Army service. They believe themselves to be in poorer health than at induction. They consider their health impairment chiefly in terms of physical disease and in general do not recognize the psychologic aspects.

The longer a man in this group served in the Army, the more likely he is to consider his health to be affected. Similarly, the men who served overseas consider themselves to be sicker than do those who did not see any overseas service. In addition to their reporting poor health, a need was expressed for medical and hospital care which is far beyond their prearmy requirements.

The vast majority of those studied are working but definite changes in their employability are apparent. More men are unemployed now than at the time of induction. The unemployed group is for the most part composed of those who were working before induction. In their subjective estimate of their reasons for not working now, the unemployed, to a great extent, attribute their failure to work to poor health. There was little indication that they were discriminated against by prospective employers because they received a medical discharge.

Overseas service was reported by 13.7 per cent of the group. This percentage may increase as time goes on. It is not possible, however, to predict at this time the effect such an increase would have on the findings of future similar studies. A special investigation of the overseas group will be undertaken in an attempt to determine whether or not they comprise a special group in terms of adjustment.

The limitations of the method used in obtaining the data are obvious. The replies received by mail from the men are purely suggestive. The results may not be a reflection of the true state of their health. Exaggerations may have been made consciously or unconsciously for a variety of reasons. However, the veterans' own evaluation of their conditions is important and cannot be ignored. The findings indicate that there was little tendency for them to report change in their conditions between discharge and the follow-up study. There is a distinct suggestion of permanence of their disorders in their own minds. Active measures will have to be taken if this attitude or state of affairs is to be influenced.

It is recognized that employment is easy to secure at this time and that adjustment in terms of employment is relatively simple now. It is not possible to predict what will happen in the future. Factors will be present which may influence adjustment in opposite directions. The end of the war may produce in some a change in intrapsychic tension and need for illness. Time alone may bring with it improvement. Increased competition for fewer jobs will exert its influence, and the socioeconomic condition of the postwar world will be an important factor affecting the adjustment of these men.

PSYCHIATRIC TECHNICS IN THE MANAGEMENT OF EMPLOYEE PROBLEMS

L. E. HIMLER, M.D.
Consultant in Psychiatry, Detroit Transmission Division, General Motors Corporation
DETROIT

Treatment of the many minor personality problems and maladjustments coming to the attention of the physician in industrial practice does not demand new or complicated technics so much as it does a more effective application of methods already at his disposal for influencing human beings and their relationships on the job. Psychotherapy is of course an integral part of all medical practice, but its special potentialities in the field of industrial relations have not received the emphasis they deserve. Not only the great number of dispensary calls which involve psychogenic disturbances either primarily or secondarily but also many of the other personality problems which harass industry could be more effectively handled if the role of the industrial physician included active and clearly defined psychotherapeutic functions. In dealing with pathologic aspects of industrial human relations the physician is constantly confronted with the need for brief psychotherapeutic technics which are both effective and practical.

Unfortunately much of the clinical psychiatry taught in medical schools is of little direct use in the industrial setting. Few of the technics learned from observing the end results of severe chronic mental disease, as found in hospitalized or committed patients, are applicable to everyday industrial practice. The interminably detailed case history records, and the involved terminology which has become traditional in mental institutions, have both contributed to the general belief that all psychiatric technics are too cumbersome and time consuming to be of practical use in industry. Along with this there is another common belief, often amounting to fear, that any attempt to streamline psychiatric methods would render them superficial and therefore useless or even dangerous when applied by general physicians to the minor nervous and emotional reactions encountered in ordinary practice. It is my purpose in this paper to present evidence which would tend to disprove such pessimistic assumptions concerning the place of psychiatric technics in industry and to uphold instead the usefulness and validity of certain types of brief psychotherapy which can be successfully practiced by the interested industrial physician without undue or excessive demands on his time.

The practice of psychotherapy does not require so much in the way of strictly medical knowledge and diagnostic acumen as it does patience and sympathetic interest in the employee as a person. Patients with personality maladjustments or neurotic tendencies usually always need more than mere assurance that they are free of organic disease. Psychotherapy begins when the physician takes interest in social and environmental factors and applies his technics for impersonal consideration of facts to the personal life of the individual. In such instances it becomes necessary to give the same attention to qualitative and quantitative aspects of emotion, stability, drives, capacity for persistent effort, initiative, maturity and motivations as the physician ordinarily gives to tissue lesions caused by trauma and bacteria. The clinical picture of the patient as a whole is distorted if the physician handicaps himself by singling out only those complaints and behavior changes which suggest physical malfunction and disregards those which in terms of neuronal circuits are functionally (electrochemically) related to attitudes and the satisfaction of emotional needs.

Because of the tremendous number of variables which enter into the emotional makeup of different individuals, it is next to impossible to set up detailed diagnostic criteria into which all the minor personality determined problems of industrial practice can be fitted. However, on the basis of the presenting complaints, personal attitudes and reactions it is usually possible to single out at least a few of the predominant emotional trends, and these often give excellent clues as to the type and extent of psychotherapy which will be required. As an example of the first step in such an approach, the following list presents in the order of frequency the varieties of psychosomatic disturbances found in the initial contacts with 40 unselected industrial workers and supervisors who appealed for psychiatric consultation or were referred for interviews:

1. Emotional instability and overexcitability under stress.
2. Rigidity, lack of adaptability.
3. Feelings of inferiority.
4. Egocentricity, overaggressiveness, lack of social consideration.
5. Inadequacy in attitude and responsiveness.
6. Love affairs, sex and marital problems.
7. Oversensitivity.
8. Pronounced feelings of insecurity.
9. Inappropriate self-protective defense reactions.
10. Habitual overuse of alcohol.
11. Visceral symptoms related to emotional tensions.
12. Poor attendance record.
13. Preoccupation over disturbing home and family situations.
14. Personality eccentricities and mannerisms.
15. Definite introvert or schizoid tendencies.
16. Poor organization, lack of regularization in habits.
17. Relative intellectual defect.
18. Special fears and anxiety reactions.

As might be expected, most of the persons in this small series had more than one symptom indicative of emotional subhealth and psychic unrest, the average being three for each employee. Regardless of the relationship between symptoms and coexisting or associated physical disorders, it is remarkable how willing and even eager the great majority of such persons are to discuss personality factors as such when the opportunity is presented. In many instances the relationship of such personal problems to lack of efficiency on the job is frankly acknowledged and adds further incentive to the acceptance of authoritative assistance and counsel.

With the stage thus set for psychotherapeutic contacts, it might be well at this point to review those methods open to the industrial physician or consultant which do not require extensive knowledge of psychiatry. In a recent book on this subject, Levine [1] listed some thirty general methods of psychotherapy which are used by the medical practitioner, and only five of these require added training and aptitude. When these are modified and adapted to fit into the industrial setting, they tend to fall into three overlapping categories: those which are an intimate part of routine procedures, those which

Read before the Section on Preventive and Industrial Medicine and Public Health at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 14, 1944.

1. Levine, Maurice: Psychotherapy in Medical Practice, New York, Macmillan Company, 1942, chapter 2.

might be termed "psychiatric first aid" and those which come into play when there is need and opportunity for extended private interviews and follow-up contacts. Some of the technics included in such an inventory are as follows:

1. Physical examinations as psychotherapy.
2. Physical therapy as psychotherapy.
3. Laboratory tests as psychotherapy.
4. Medicinal treatment (including placebos and sedation) as psychotherapy.
5. Guidance, interpretation and medical advice.
6. Giving diagnostic information with authoritative firmness.
7. Reassurance.
8. Minimizing or ignoring certain symptoms and attitudes.
9. Emphasizing a balanced daily routine (work, rest, food, recreation).
10. Drawing attention away from symptoms by praising healthful attributes.
11. Suggestive therapy.
12. Development of hobbies.
13. Encouraging socialized living and participation.
14. Pointing out opportunities for healthy identifications.
15. Sympathetic listening; confession and ventilation.
16. Provision of acceptable outlets for aggressiveness.
17. Provision of acceptable outlets for fears and inferiority feelings.
18. Provision of acceptable outlets for frustrated affective needs.
19. Lessening environmental strain, both industrial and non-industrial.
20. Using consultations with wife, relatives or home physician as psychotherapy.
21. Transferring to new occupation or environment.
22. Recommending additional training.
23. Changing attitude of supervisors.
24. Provision for rest or change through leave of absence.
25. Discussion analysis and desensitization.
26. Persuasion and reeducation.
27. Referral to consultant or specialist as psychotherapy.

Such a list could be extended indefinitely, but it must be emphasized that the effectiveness of all such measures depends as much on the individuality of the physician as the patient. The extent to which psychotherapeutic technics are used and the order in which they are woven into the physician-patient relationship will depend largely on specific needs and circumstances in each individual case. With neurotic patients as with children, emphasis should be placed on simple, workable procedures in which the patients participate, rather than on negative aspects or prohibitions. The key significance of the first interview should constantly be kept in mind by the psychotherapist. Some contacts are made much more effective if the physician stresses the necessity for a follow-up interview or even calls the patient in before he would ordinarily return with further complaints. Even in those instances in which the nature of the psychiatric problem goes beyond the scope and responsibility of the industrial physician, referral and cooperation with outside consultants can be greatly facilitated when inplant contacts are established in this way.

Preliminary observations from the application of these methods to the 40 cases mentioned indicate that good therapeutic response was obtained in 45 per cent, fair results in 38 per cent and no significant improvement in 17 per cent. Practically all in the third group were found to be in need of more intensive therapy than is possible on an inplant basis, and 3 have terminated their employment up to the time of this writing. Although observation and treatment of these individuals is still in process, it is of interest that the number of contacts per case was only 3.3 and that the average time spent over a six months period was a little under one and one-half hours per case. This does not seem excessive in comparison to the time often required for repeated visits to the physician for minor complaints, not to mention the inefficiencies on the job, when no effort is made to influence personality and emotional factors. It is especially gratifying to note that some degree of improvement in job relations was effected in 10 cases after only two interviews. As a rule when therapy is effective, follow-up contacts are progressively much shorter than the initial ground breaking interviews.

While industrial physicians and consulting psychiatrists are by no means the only individuals with personnel functions in industry who employ psychotherapeutic technics, it goes without saying that by virtue of their medical training and clinical experience they alone are best qualified to take authoritative leadership in the application of such methods to management and employee problems. Beyond enlarging the scope of their services to individual patients by more actively employing psychiatric insights, industrial physicians have another and still larger obligation—that of teaching both by example and in more formal ways the philosophy of this approach to management, foremen, employment interviewers and last but by no means least their own assistants, the industrial nurses.

LABOR-MANAGEMENT RELATIONSHIPS IN INDUSTRIAL HEALTH PROBLEMS

J. J. BLOOMFIELD, B.S. IN ENG.
Senior Sanitary Engineer, U. S. Public Health Service
BETHESDA, MD.

Industrial hygiene as a science and as a public health service has been developed with the objective of protecting and promoting the health of the working population in an industrial system. Its development has been the result of a parallel growth of responsibility on the part of management and governmental agencies. Management has had an economic interest in preventing accidents, disease and premature death. Governmental agencies have taken action in solving industrial health problems because such action is a proper obligation of public agencies. Labor, as represented by both organized and unorganized workers, has had a lesser role in this development, largely because strong organization is necessary for effective action, and until recently unions have not been well enough established to allow them to give attention to the advancement of special welfare programs. Today, more than ever before, management is concerned about the workers' health because every available adult is needed on the job to produce. Labor unions have now gained the means and the leadership to make possible the initiation of progressive action in the health field.

There are many difficulties in the way of effective labor-management cooperation in applying industrial hygiene knowledge, which must be recognized at the outset in attempting to bring these partners together. Since management and labor both have so much to gain by cooperative and intelligent application of industrial hygiene methods, it is tragic that so much controversy, misunderstanding and resistance on both sides still exist in many industries.

From the Industrial Hygiene Division, Bureau of State Services, Bethesda, Md.

Management has developed health and safety rules and regulations in most instances without consulting the workers. The workers have at times used their union strength to oppose measures which would benefit them. There are still many companies and unions whose activities show no evidence of consideration of the health needs of the workers and the necessity for a healthful working environment. Despite new signs of increased interest in workers' health on the part of unions, some segments of labor are apparently still more concerned for compensation benefits than for prevention of the conditions which caused the compensable injuries —injuries which can never be compensated by cash benefits. On the other hand, attitudes of management toward industrial hygiene run the entire gamut from paternalism to neglect. In general, most large industries have an enlightened approach to industrial health, which insures to their workers high quality service and constant attention to the working environment.

What is really needed on the part of both labor and management is a new policy—a new attitude toward this question of industrial health. There is no reason why some formula could not be devised to harness the power of labor organizations with the splendid organization which management has created in many plants, so that the two will not oppose each other but pull together as a team toward the common goal.

Whatever gains management has made in the acceptance of progressive industrial health programs have been the result of many years of slow education—experience earned the hard way. Because of the requirements imposed by certain types of workmen's compensation acts, management first began to establish medical departments solely for the treatment of traumatic injuries, in accordance with the requirements of the laws. Gradually, management realized that there were other phases of the problem in need of attention, and it began to extend its surgical treatment work into such functions as preemployment and periodic physical examinations and, in recent years, medical and engineering control of occupational diseases and job placement. At the present time attention is being devoted, on the part of some of the larger concerns, to such problems as general illness among workers and such factors as fatigue, dental hygiene, nutrition, mental health and similar adult health problems.

It would seem that we are now passing from the strictly machine engineering age to the human engineering era. In other words, where in the past attention was given mainly to the improvement of machinery and processes, today management is beginning to be concerned with the economic waste resulting from the failure to provide protection for its workers against controllable or preventable occupational health hazards. Not all of these advances have been achieved without trials and tribulations. Perhaps it was necessary for a national emergency such as the present one, with its emphasis on production and the need for the conservation of manpower, to point up the importance of the human element in a highly industrialized nation.

Labor has just demonstrated how an effectively organized group can function successfully on the political front. This too has taken many hard years of work to achieve. There is no reason why labor cannot accomplish similar tasks in relation to other gains, and especially on the social front. Today labor is beginning to show an interest in health and safety services, and it portends to become widespread, vocal and specific. The unions are recognizing more and more that their contributions to the well being of the individual worker must parallel their activities for economic betterment and conditions of employment. However, labor should go slowly and recognize that it has a good deal to learn in the field of industrial health. It should work for a constructive program as an end unto itself and not use health problems merely as a means to obtain concessions, such as higher wages and shorter hours. It will probably not be necessary for labor to go through as long a period of education as it took management, since many of the patterns in this field have already been developed, but it would be well for labor, and especially its leaders, to study the various problems carefully before striving for demands either through collective bargaining or through some forms of legislation. Labor will find official and nonofficial health agencies ready to assist in this educational process.

Recent efforts to obtain labor-management cooperation in many fields vital to the nation's economic life give promise, so that ultimately these two powerful forces may come together in a mutual endeavor for the common good. Some industrialists may feel outraged at the mere thought of giving labor some voice in the management of any part of its affairs. On the other hand, many have recognized that the rank and file workers have resources of intelligence, ingenuity and enterprise which industry can utilize. By the intelligent use of these resources, management will not only do a better production job but at the same time will take a real step forward in establishing the worker as an individual, thereby doing away with one of the main difficulties in the field of labor relations.

Such action does not necessarily mean that labor will run management's business or that such a business will be run by a committee of labor and management. After all, management owns the plants and provides for safety and health in accordance with certain legal requirements. Such being the case, no one has the right to force management to do certain things when it is only management which is held responsible. In other words, nothing must be done to interfere with or reduce management's responsibility, so that it may direct the health and safety program properly. On the other hand, there is no reason why labor should not contribute in an advisory capacity many helpful suggestions which could be adopted and carried out by management. In fact, as has already been stated, there are many ways in which management and labor can work together, not only in the field of industrial health but in the field of production, training of personnel and in similar ways.

However, cooperation between labor and management appears still to be in its infancy, in spite of the impetus given to such cooperation in the present need for all-out production. More education in the technic of cooperation is needed for both industry and the unions, especially at the plant and local union level. The pattern is cut—it can fit and should be used much more widely and in more diverse fields than it is now, particularly in health and welfare activities, which should be of permanent concern to labor and management.

Labor-management committees sponsored by the War Production Board have served a useful function in stepping up production for the war effort. However, where they have functioned in the permanent health and welfare activities, the results have not been impressive. In those industries where good labor management relations already existed, some progress has been made in safety and health programs. In others, attention to workers' health has been perfunc-

tory. In most instances emphasis has been placed on accident prevention—the one field which has been an established, legally protected activity over a period of thirty years. New opportunities for the improvement of working conditions and workers' health have not been explored and exploited intensely by the labor-management committee. F[illegible]; which have been received from th[illegible] Board show activities for safety, better nutrition, better sanitation and general health promotion, in about that order of importance. For example, a large automotive vehicle company employing approximately 10,000 workers and the union, a U. A. W.-C. I. O. local, formed a War Production Drive Committee in 1942. The general committee and numerous subcommittees each had equal labor and management representation. The health and safety subcommittees reduced the accident frequency rate by 25 per cent in one year. Through the action of the labor-management committee, a safety engineer was employed full time. The reporting of unsafe practices and unsafe conditions to the health and safety subcommittee was encouraged. Despite an increase in man-hours worked by nearly a million and the addition of some 500 new workers, the accident frequency rate of 23.9 disabling injuries per million man-hours was reduced to 18.6. The committee also sponsored a vaccination program, with the aid of the medical department, and 3,000 workers were vaccinated. Chest x-ray examinations were made available to all employees on a voluntary basis.

Other evidence shows that health and working conditions are subjects of vital importance to the workers, although there may be no organized effort on the part of workers to improve them. This is attested by a recent statement from a labor-management committee which questioned some 1,300 new employees in a plant relative to the subjects they considered most important to their welfare. Some 36 per cent of these new workers stated that safe and healthful working conditions were most important, stating that employment was the next important subject, with about 16 per cent indicating their concern with this factor.

Mr. V. P. Ahearn, industry member of the National War Labor Board, recently stated:

> There is hardly a major case coming before the War Labor Board which does not involve, at one stage or another, a demand that something shall be done . . . to improve industrial health. Even though the demand may not meet the objective, even though it may be unworkable, nonetheless the reality of that demand is something that practical men in industry cannot ignore.

There are some leaders in both labor and management who, although not condemning labor-management committees in outright fashion, still feel that their scope has been restricted to such an extent that these joint programs have been vitiated. For example, Mr. Robert Watt, labor member of the National War Labor Board, feels that the work of these committees has been restricted to the old company union function of concentrating on ways to obtain more effective effort from the workers. According to him, labor does not object to such results but regrets that this important function was not knitted into the fabric of union representation in accordance with established public policy of a democratic nation. Mr. Watt feels that collective bargaining has served already to accomplish far more than these committees can do. He feels that the present National War Labor Board itself is the best demonstration of the value of economic democracy. Since this board has accredited representatives from management, labor and the public, such action places on the labor movement the necessity of maintaining effective and responsible leadership. It has made the interested parties in industrial relations shoulder the obligation of facing and solving issues. According to Mr. Watt, on any question of any importance there should be participation by representatives of labor and management, with authority to help analyze problems, seek solutions and formulate remedies.

This brings us to the role which collective bargaining has played in the field of health, safety and insurance. The union agreement negotiated through collective bargaining between management and labor offers one channel for the improvement of industrial health and working conditions. Health and safety provisions are specified in a number of existing contracts, a practice which was followed by many unions for many years. However, a study of the health and safety clauses shows that these provisions have been made in order to protect workers from unfair application of company regulations, to right some specific grievance or to correct some single outstanding hazard. As far as one can determine, no union agreement provides for a broad industrial health program in the industry with a view to long-term reduction of sickness and promotion of positive health. The health and safety clauses recently written by the U. A. W.-C. I. O. Health Institute for the guidance of local unions in the negotiation of future contracts are the nearest approach to such a contract. The chief provisions of these proposed health, safety, group insurance, and compensation clauses deal with such things as the formation of health and safety committees with equal representation from labor and management and discusses the duties of such committees with reference to the evaluation and control of the industrial environment. Such functions as reporting of injuries and illnesses to the committee, the provision of adequate emergency medical services, free periodic physical examinations and special provisions for women in industry are also highlighted in these suggested clauses. These clauses are perhaps the first attempt to negotiate for a broad industrial health program, but in their present form they will need considerable revision, since some of the demands are unnecessary or impracticable, while others, if not administered properly, would tend to impair the rights of management.

PHYSICAL EXAMINATIONS

In general, existing health and safety clauses in union agreements fall into three categories: (1) provisions with regard to physical examination of workers, (2) safety and health provisions and (3) insurance benefits. Let us consider the first and most controversial point—physical examinations. Until recently, neither management nor labor has fully understood how to utilize properly the physical examination as a technic for the improvement of the health of the industrial worker. In the past, routine preemployment and periodic examinations have been made a company requirement in order to protect management in compensation litigation and to reduce the costs of insurance premiums. Labor, on the other hand, has insisted on contract clauses or laws designed only to protect workers against unfair use of the examination rather than making it a health service to the worker.

We must recognize, first, that the physical examination is more than a medical problem. It is also a socioeconomic problem. The man who has spent his working life in one industry and has acquired seniority

and a higher wage scale cannot be expected willingly to accept placement in a less arduous but less remunerative job, even though it would save him from premature death due to a heart condition discovered in the examination. Enlightened employers recognize this problem, even though they have not yet provided the answer.

Perhaps this is one of the many problems in health and welfare which can be solved satisfactorily only by national and state legislation to provide adequate economic security for the workers handicapped by accident or disease. We have cases on record in which an attempt has already been made to deal with situations of a somewhat similar character. For example, when the state of Pennsylvania adopted its occupational disease compensation act it recognized that there were already many workers in the state's industries who had acquired certain diseases of occupation prior to the date when the law became effective. It also recognized that the last employer would be unduly penalized if he was made to carry the entire burden of the compensation to which some of the workers would be eligible, even though they might not have been employed in his plant long enough to acquire such diseases or conditions. For this reason the state of Pennsylvania created a special fund of $100,000 out of the general tax fund and gave it to the State Workers' Insurance Board for payment into a state workmen's insurance fund for the credit of the Second Injury Reserve Act. This fund was to be used for a perid of ten years and was an attempt to apportion equitably between the last employer and the state fund the amount of money due a worker. After the expiration of a ten year period, the employer was to pay the full compensation for disability or death.

It has also been suggested by leaders in the field of compensation administration that such funds be employed to take care of older workers whose earning capacity has been lowered. To take care of such contingencies it will be necessary to maintain a solvent second injury fund. This could be done by several methods, one of which would be through general taxation.

The war emergency has stimulated better use of the physical examination by management, since the shortage of manpower has made it necessary to accept for employment thousands of physically handicapped workers and others whose general health is substandard. It is unfortunate, therefore, that some segments of labor still resist actively the requirement for routine physical examinations. For example, there is one powerful union which has even written into its contract with management that no preemployment physical examinations should be given. As a result of this attitude, many of the plants operating under such a contract have experienced an enormously high labor turnover, since they have been forced to hire thousands of persons whose handicaps could not be studied and related to the job requirements.

It is difficult to understand such unenlightened attitudes of some labor leaders. If the purpose of a national health program is to attain national physical fitness for the people of this country, greater use must be made of a careful objective medical examination of more individuals. Its use in industry has contributed and can contribute greatly to public health if the problems associated with the physical examination of workers are solved. These problems can be solved if all interested groups get together and put their minds to it.

Management, labor and the medical profession have taken this step. The Council on Industrial Health of the American Medical Association in 1944 called together representatives of the American Federation of Labor, the C. I. O., the National Association of Manufacturers, the U. S. Chamber of Commerce and the casualty insurance companies. This group of competent authorities defined the purpose, scope, procedure and proper use of the physical examination. Their report has already been approved by the American Medical Association and by the other interested groups. Thus, management and labor have an authoritative guide to the constructive application of preventive medicine. Let us hope that it will be used.

The most significant feature of this guide is the definition of the purpose of the occupational physical examination. This report states that:

> The purpose of industrial health programs is to promote and maintain the physical and mental welfare of all industrial employees. Health examinations in industry are a means to this end.
>
> Unjust or questionable exclusion from work through improper application of the findings on health examinations in industry is against the public welfare and contrary to sound industrial health principles.
>
> From the public and industrial health standpoint, the only absolute bars to immediate employment in nonhazardous occupations should be:
>
> 1. Communicable disease.
> 2. Mental illness in which impaired judgment or actions prevent cooperative effort.
> 3. Incapacitating injury or disease.
>
> Other considerations related to employer liability, workmen's compensation, factory acts and health codes must be determined separately for each jurisdiction.

The liberal policies enumerated in this report on the use of medical records and appeals are worthy of special attention. These are too long to reproduce here, but, with regard to the preservation and use of records of industrial health examination, the confidential character of such records is to be rigidly observed and access granted only on written consent of the worker. However, I should like to reproduce the exact words of this report on the important and previously troublesome subject of review and appeal. On this point the report is very clear and specific, and states:

> When a worker has been physically examined, and the doctor making the examination reports that he is physically unfit for any work or for certain classes of work, which report may have an adverse effect on the employment of such worker, the following procedure shall apply:
>
> The worker may designate a physician of his choice and request a review of the findings made by the examining doctor. These two physicians may proceed to render a joint report. If they are not in agreement, then a third physician, agreed on by the two reviewing physicians, shall be selected and his findings shall be final. If the two physicians cannot agree on a third physician, then the chairman of the industrial commission in the state in which the plant is located shall make the selection.

HEALTH AND SAFETY

Undoubtedly industry and unions will continue to include health and safety provisions in their contracts, perhaps for some years to come. The purpose should be to broaden these provisions to encompass a comprehensive industrial health program in which both management and the workers will participate. As a guide, I should like to suggest that the basic health considerations in collective bargaining should include:

> 1. A labor-management committee, of equal representation, to advise the union and management on health needs of the workers and on ways and means to meet the needs.

2. In-plant medical services, adequate in scope and quality, and acceptable to both labor and management.

3. Preplacement and follow-up physical examinations conducted under the policies outlined by the report of the Council on Industrial Health of the American Medical Association and supplemented by careful job analysis for proper placement.

4. Routine industrial health surveys of working conditions by official industrial hygiene agencies or similar disinterested agencies acceptable to the committee.

5. Compliance with recommendations made by the surveying agency for the improvement of working conditions.

6. Promotion of special public health services in the plant for the improvement of individual health, such as nutrition programs, mental health services, dental care, communicable disease control and health education.

The major health problems of the working population, however, cannot be solved by union agreements or by management or by labor alone. A comprehensive national health program administered by state and local governments would meet the needs of all groups for health and medical service, hospital care and prevention of disease. Present federal and state laws on the subject of health maintenance are undoubtedly inadequate and are certainly not uniform. Labor, on the whole, is dissatisfied with present legal provisions of health and safety and for their enforcement. That is why, of course, labor is attempting to gain such benefits through collective bargaining procedures. Recently the Congress of Industrial Organizations passed a resolution on national and state legislation dealing with health and safety. This resolution calls for action on an educational program to inform the general public, as well as its own members, as to the desirability and necessity of providing and enforcing adequate standards of protection against the hazards of employment.

There is no doubt that our present laws on this subject need to be strengthened. Take, for example, our present provisions for industrial hygiene in the various states. Although considerable progress has been made on the part of the states during the past eight years in this field, still, even today, there are nine states which have no industrial hygiene services as such, and the thirty-nine states which do provide such services spend only approximately $1,250,000 for such activities. This sum, half of which is allotted to the states through federal grants-in-aid, permits but a small coverage in the way of services to the fifty odd million workers of this nation. Obviously there is a need for more funds, more state and local financial participation and more trained professional personnel to do an adequate service job in our industries.

For these reasons it would be far more preferable to revise and strengthen our present laws on health and safety requirements and especially their enforcement provisions so that benefits of such laws could be applied to all workers rather than to those who happen to be strong enough to obtain concessions through contracts. To this end we need the support of labor as well as management, with both getting behind proper legislation which would provide state health authorities with the necessary funds and trained personnel and the authority to do their job effectively. Such action is a far more democratic method of accomplishing the desired objective than through collective bargaining procedures alone and in addition would serve the millions of workers who are unorganized. Through such collective action on the legislative front the rights of neither management nor labor, nor their free functioning, will be impaired.

Any action taken, however, must be preceded by careful study of present industrial health laws, regulations and services by labor union leaders, with widespread discussion of proposed action among all union organizations, in order that there may be a unified attack on the problem. A first step in developing the required understanding at all levels of union organization would seem to be the appointment of individuals to the executive staffs of national and state union organizations, and to each international union staff, with responsibility for full time attention to health. Such persons should be given proper orientation in the health field through contact with health agencies and, if possible, through organized study of industrial and public health. Their function would be to maintain close working relationships with all health agencies and represent their organizations in all cooperative planning of activities among agencies concerned with health programs. These health advisers could assume leadership in organizing educational programs on health for union members through all the channels of union organization and activity.

In conclusion, I would urge that those of us who have an interest and an obligation to work with unions should help them in every way possible to attain their objectives, first being sure that sound objectives are established through full understanding. At the same time we should lend our aid in helping other groups to appreciate the fact that unions have a contribution to make and that statesmanlike cooperation can be expected where confidence is established on all sides.

LOCAL ORGANIZATION FOR EMERGENCY SERVICES

ARTHUR U. DESJARDINS, M.D.
ROCHESTER, MINN.

In this country perhaps more than in any other a fashion, a song, a word, an expression, a mechanical gadget or an idea, when it happens to strike the popular fancy, sweeps over the country like a prairie fire. Many of these pass and disappear as rapidly as they came, but others, when they are bolstered by an outstanding personality or by systematic and persistent advertising, may continue indefinitely and may become, so to speak, a part of our folklore. Some of these things, especially gadgets and ideas which are associated with the use of gadgets, are immediately taken up by commercial exploiters who proceed to "cash in"; and as the cash rolls in, or even before, a corporation is organized, partly to hide the identity of the exploiters and partly to increase the take by all the means known to high pressure exploiters. One of the principal methods is advertising, which, to a considerable extent, has become the art of misleading people into acquiring things good or bad, whether or not they are needed. In fact, one of the main objects of advertising is to induce people to regard as desirable or necessary objects which are not at all essential or which may even be harmful.

During the past quarter of a century, or since the first world war, a peculiar situation has developed. Whenever a person drowned, or when breathing ceased for any other reason, the relatives immediately called, not a physician, but the fire department or the police department, because one or the other of these departments maintained a rescue squad which was subject to call at a moment's notice. Sometimes a physician also was called, but often enough the physician was busy elsewhere or, when he arrived on the scene, the rescue

From the Section on Therapeutic Radiology, Mayo Clinic.

squad of the fire or police department had already taken over the situation as well as the responsibility. Or perhaps the demands of a busy practice did not permit him to disregard them in order to take charge of an emergency situation which might detain him for an hour or longer. Gradually this practice has grown until now it is the accepted method of dealing with emergencies of this kind, not only in large cities, but even in small cities throughout the country.

How and why did this practice develop? The idea of organizing rescue squads among firemen and police officers was a perfectly natural one. During the course of many fires some persons, including some of the fire fighters themselves, are overcome by smoke or chemical fumes of one kind or another. The importance of immediate attention for these persons is so great that every minute counts. Any delay may mean the difference between life and death. Hence the organization of rescue squads was an eminently sound idea. Moreover, fires do not occur frequently, and members of fire brigades have much time on their hands, which they occupy in refurbishing their equipment or polishing the seats of their pants. By the very nature of their work police officers have less time to waste, but some of them have plenty of time to play cards, especially at night, when life in a police station often is a boring experience.

A second reason for the organization of rescue squads of firemen or police officers was the example provided by many large industrial plants, which, in order to diminish the loss of labor resulting from injuries incurred by their workmen, to diminish the claims for injuries sustained in the course of employment or to meet the requirements of the compensation laws of some of the states, organized and maintained, in connection with their welfare service, a department for the emergency treatment of injuries as well as rescue squads to deal on the spot with the effects of certain kinds of accidents. Thus telephone companies found it expedient to train squads to rescue some of their linemen through whom a strong charge of electricity had passed. As is well known, when contact with a live wire causes an excessive charge of electricity to pass through a person, the immediate effect is either fibrillation of the cardiac muscle or spastic contraction of the heart as a whole, according to the charge of electricity; and respiration ceases. Artificial respiration, when promptly instituted, can save many victims. But to wait until a physician can be called and until he can arrive would be to lose the chance of saving some of these men. Much the same is true of men working in mines who are affected by chemical fumes, by cave-ins or by electrical injuries. Large steel mills also have maintained departments for emergency treatment of all kinds.

Perhaps a third reason for the organization of these squads was the invention of an automatic breathing machine which was known as the pulmotor. This machine having been invented about 1911, what could have been more natural for its manufacturers to do than to persuade fire and police departments to organize rescue squads whose members were trained to use the pulmotor? Although the precise relationship between the invention of the pulmotor and the organization of special squads of firemen or police officers cannot now be absolutely established, certainly the rapid and widespread organization of these squads and the increasing use of the pulmotor or other artificial breathing devices of the same general description was not a coincidence.

As it was first designed and used, the pulmotor actually was dangerous because, being built on the principle of suck and blow and the degree of suck and blow not being absolutely controllable within safe limits, the possibility of injuring the lungs by excessive pressure was not eliminated. There is reason to think that, during the early stage of its development, the pulmotor may have done as much harm as good. Another dangerous possibility was that, as the result of publicity and the misleading claims which were made for this device, there was a strong tendency, when an accident occurred, to neglect ordinary and well known methods of artificial respiration, which do not require mechanical apparatus of any kind, and to wait for the pulmotor squad. The effect of this tendency was that, as a result of the delay, many persons died who might have been saved if more prompt measures had been taken. Later, the dangerous feature of the pulmotor, which resulted from the absence of an effective means of controlling the pressure of air, was eliminated when an automatic regulator of pressure was added.

Since then other similar devices built on the same general principle and incorporating automatic control of air pressure have been designed and placed on the market but, unless they are employed by some one who is thoroughly familiar with the process of respiration under normal as well as under pathologic conditions, mechanical apparatus of this kind may be, and no doubt often is, quite ineffective. However, unscrupulous advertising and high pressure salesmanship have led the general run of people to have an excessive and unwarranted faith in these devices. Indeed, the faith of Americans in mechanical gadgets of all kinds is astonishing and rather childish. But this is not the point which I should like to stress. It is about time to return to our rescue squads of firemen and policemen, who, in a preceding paragraph, were left peacefully enjoying their game of cards.

On the whole, men working in large industrial establishments or in mines or employed by public utility companies are cared for as well as they could be under any circumstances. What interests me at the moment is the provision of a similar grade of care for the public at large, and it is this phase of the problem which I should like to discuss.

To my simple mind, arrest of respiration and of heart action, whether caused by drowning, by an excessive charge of electricity, by smoke or gas fumes or by any other means, is as much a medical problem as nephritis or pneumonia. But accidents of this kind often occur under circumstances which constitute a special problem. Rescue squads of firemen or police officers are only a makeshift arrangement which is far from rational. The fact that these squads receive special training and that often their ministrations are more effective than would be those of physicians who have not had special training and experience in methods of resuscitation is beside the point. No matter how well firemen or police officers may be trained to perform artificial respiration or to run a mechanical breather, they cannot be expected to know the difference between drowning, an attack of heart disease, cerebral concussion and cerebral hemorrhage. Of course, special circumstances may give an intelligent layman some idea of the nature of such an accident, but it is not a rare occurrence for a police officer to mistake cerebral hemorrhage for an excessive dose of alcohol.

For many years, as a member of the Council on Physical Medicine, I have had the opportunity to hear many discussions of the problem of resuscitation and of many phases of this problem. More and more it has

seemed to me altogether incongruous that the present situation should have been allowed to develop. Lately my thoughts on this subject have crystallized in a certain direction and I am taking the liberty of submitting these thoughts for your consideration. It seems to me that this situation could and should be corrected and that all rescue activities, outside of coast guards and other similar guards at public beaches, should be reorganized on a different basis.

The medical profession should assume the responsibility for organizing emergency or rescue squads to take care of resuscitation and other first aid measures, as well as the removal of emergency cases to hospitals. This would necessarily mean one of two things: either that the physicians of each community should, on their own initiative or on the initiative of the county or state medical association, organize an emergency service for full time duty or that the state departments of health should be made responsible for the organization and operation of these emergency services. Physicians selected for this service might perhaps be on duty for a week at a time, one group during the day and one group at night, and have at their disposal an ambulance, fully equipped to deal with any emergency that might arise.

It is true that, at the present time, hospitals have ambulances and interns or residents who take care of emergency calls; but the young physicians who take care of these calls have had only limited training in medicine and have not had special instruction in resuscitation, whereas the emergency services or squads which I have in mind should be composed of experienced physicians, with special training in resuscitation and all other emergency situations. An alternative, or perhaps only a supplement to the foregoing suggestion, is that each city should have a centrally situated emergency medical station. This would be most important in cities with a population greater than 100,000 and especially in cities with a population greater than 1,000,000. In the largest cities it might be necessary to have substations strategically situated according to density of population.

The organization and supervision of such highly trained medical emergency and relief units should be undertaken by the medical profession itself. However, in the case of central emergency stations and substations the municipalities or the states should be persuaded to furnish buildings and necessary equipment, including ambulances and so forth, and should also pay the salaries of the physicians and all other expenses, subject to reimbursement by the patients or their relatives. To allow the present fashion of police and fire department squads to attend to medical emergencies seems entirely incongruous.

It is realized that such a step could not well be taken now or until the end of the war, but there is no valid reason why plans should not be made to adopt this principle and implement it as soon as the war has ended. If the American Medical Association were to adopt the principle of this plan and so inform the medical societies of the different states, this action would have great influence. Naturally, it would take time to apply the principle, especially in the larger cities, but, as soon as the circumstances allow, steps should be taken in this direction.

One way to accomplish the desired result, once the principle has been adopted by the medical profession, would be to undertake a strong educational campaign, which should be continued until the public demands action. It is possible that, in order to induce municipal or state politicians to provide funds for buildings and ambulances and to pay physicians instead of firemen or police officers, some kind of coercion would be necessary. But if an adequate educational campaign should be conducted, the acquiescence of political bodies would be imposed by the public demand. The most effective way to obtain political action is to build a fire under a legislature and to keep the fire going until the legislature is forced to move.

PSYCHIATRIC REACTION TO AMPUTATION

LIEUTENANT COLONEL GUY C. RANDALL
MEDICAL CORPS, ARMY OF THE UNITED STATES

JACK R. EWALT, M.D.
GALVESTON, TEXAS
AND

LIEUTENANT COLONEL HARRY BLAIR
MEDICAL CORPS, ARMY OF THE UNITED STATES

Many surgeons have emphasized the importance of the psychiatric or psychologic components of the total problem of limb loss, stump construction and training in the productive use of prosthetic devices. As an example, MacDonald [1] has stated that "the surgeon has a definite responsibility in stimulating confidence and in teaching the man to use his appliance. Overoptimism on the part of the patient at the beginning is sometimes followed by an equal degree of depression when he feels the weight of the appliance and he has his first difficulty

with his overenthusiastic attempts at walking." In spite of this attitude the reported studies on the psychiatric reaction to amputation consist, for the most part, of studies of phantom sensations. The complication of "phantom limb" has received much attention from many authors.[2] There is no general agreement as to the peripheral or central origin of these phenomena, but most writers agree that there is at least a psychologic component in all such cases. We have attempted to resist the temptation to write on this phase of the problem because we feel that the individual's total reaction to his injury and his adjustment to it are of greater importance to his future usefulness and comfort than any sensations that seem to come from his missing member.

METHOD

The 100 patients studied were selected at random from the card file index in the orthopedic section. Patients who had been referred for neuropsychiatric consultation were excluded, only those patients considered "normal" by the physicians and nurses remaining in the series. The purpose of the study was explained to each patient, and each was told that he could refuse to participate if he wished. No one refused and most patients seemed anxious to participate. A detailed social history was taken by a Red Cross social worker, and a Rorschach test was administered by a psychologist. The Rorschach records were scored and interpreted on a "blind" basis by one of us. Psychiatric evaluation of the data was made by another and the orthopedic care administered by the third.

The data were pooled and evaluated only after all had been collected. The series included 76 soldiers injured in battle and 24 injured in accidents incident to their training or noncombatant duties (table 1). The age average was 26.7 years (table 2 and the chart). All were well trained troops. It will be noted that lower extremity amputations were most frequent (table 3).

RESULTS

The reactions seem to fall into three fairly definite phases in terms of time: (1) the first or immediate reaction, (2) the intermediate period, beginning as the

patient emerges from the shock and general reaction to the injury and ending when he masters his prosthesis and returns home, and (3) the late or final reaction, beginning when he goes home to reenter the civilian world.

The immediate reaction to the injury depends somewhat on the circumstances of the injury. Men who have survived an engagement or explosion with high casualties feel that they are so lucky to be alive that they have little concern about the details of the future. Whether this attitude will persist outside the hospital is a matter of great interest to us. Persons injured alone or as the only casualty at the time of their immediate group are more apt to be a little depressed and resentful at their "luck," but they still feel honorably wounded and have a good morale in spite of their doubts and misgivings about the future. Patients who have sustained injuries while absent without official leave or drunk or through carelessness generally have a poorer attitude, are more inclined to be depressed and resentful and are more apt to be disciplinary problems in the ward. The medical men and nurses in the

aid and evacuation centers do much to aid the battle casualties in their initial adjustment. They usually discuss the use of prostheses, the training program and so on with these men at the time they learn of their injury. When one considers how busy they are it is worthy of high commendation that they take the time for this effective on the spot psychotherapy. We have no doubt that the high morale in the interior hospital is in part due to the fact that the men come with high hopes of regaining their usefulness as effective producers in our society. Pain is not the immediate sensation. Those not rendered unconscious at the time of the injury state that the extremity is numb, and some try to use the extremity before they note its absence. Most of this group state that the pain starts when they notice that the extremity is gone. Many patients become aware of the loss after they have had morphine and are in the aid or evacuation station. The phantom sensations seem to start at about this time. Many soldiers are fatigued and hungry when injured and are quite ill for a few days after injury. Persons in this group give little attention to the injury and often note the loss of the extremity after they begin to improve. The patients we have studied in detail have been in the later part of the immediate reaction or in the intermediate phase. One of us has observed many patients at the aid and casualty stations, but more detailed observations at this level are indicated.

The next or intermediate phase comes with recovery from the general effects of the injury. Almost all patients need revision of the stump, repair of the flap, treatment of infections in the stump and so forth. Pain incident to these manipulations is often severe and frequently interpreted or felt as pain in some part of

Total age distribution.

the missing member. These factors focus the patient's attention on his injury, and at this time doubts, uncertainties and depressive symptoms appear. Many are much concerned over the anticipated reaction to the limb loss by their mother, wife or sweetheart. Of interest is the fact that no patient in this series mentioned any concern over the father's reaction to his injury. We believe that this intermediate period is the critical one. At this time we have the anxieties, the depressions, the battle dreams and the seeking of relief in alcoholism. Nurses and ward personnel will almost invariably tell you that these patients have the highest morale of any group in the hospital. Many patients assure you that they feel fine and have no worries,

present or future; in fact, one suspects that they feel too good. By this bravado they try to avoid questions and thus cover up the doubts and uncertainties which they do have. Once rapport is established they talk freely, and most of them are relieved at a chance to discuss their feelings, if only for a few moments. Tables 4, 5 and 6 show the incidence of feelings described as shame, self pity, lucky, depression and

worry over mother and family in the immediate and intermediate phases of their adjustment to injury. A more objective evidence of the state of tension, uncertainty over the future and doubts about their future status as men is reflected in the Rorschach study. The Rorschach revealed that the patients in this series show an unusually high incidence of anxiety of the so-called free floating type. This finding in the Rorschach test has been thought to represent anxiety and uncertainty about one's ability to adjust to the environmental and emotional demands of his future life in terms of the changes going on within himself. We have compared the occurrence of this finding in our cases with two other series in the files of one of us. One, (table 7) a random selection of 100 cases from a series of records on 200 selected soldiers in basic training, 100 of whom were neuropsychiatric casualties and 100 well adjusted to military life and a second unselected series of 100 cases taken from the active neuropsychiatric consultation files of one of us. (The records reviewed were all of those filed under A, B, C, D and some of E). The anxiety category just mentioned occurred approximately twice as often in the amputation cases as in the two groups used as "controls." The Rorschach tests in the amputation series show serious psychopathologic conditions in 50 per cent of the patients and anxiety in 67 per cent of the total series. The Ross Rating Scale (table 8), which is a compilation of various Rorschach signs, indicated serious psychopathologic conditions in 60 of the patients. The clinical evaluation indicated that about 64 per cent were having some difficulty in adjusting to their total life situation, the injury being an important part at the moment, and that 65 per cent were showing clinical signs of anxiety.

Ninety-five per cent of these patients had phantom sensations of some type (table 9). The symptoms vary from feeling that the limb is normally present to sensations of cramping, aching and itching. The fear that the phantom sensations were abnormal and represented insanity observed by Riddoch [3] was not observed in this series. These soldiers assumed that the sensations were normal and in most instances referred to them as "phantom limbs," having been educated by the hospital personnel and by other patients. The acceptance of one another's injury and their acceptance by the people in the ward and in the local community has much to do with their good morale. The uncertainties are of the future, where they anticipate and fear stares, curiosity and sympathy by the home folks and difficulty in occupational adjustment.

There is a tendency for patients who lose their legs to feel that the arm amputees are more fortunate, and the reverse is true. Many are doubtful of their ability to return to previous menial tasks because of the fatigue that accompanies prolonged activity with a prosthesis.

The individual's previous adjustment seems to be of great importance in determining the adaptation to the injury:

Patient X, a leg amputee, had been a successful cattleman prior to service. On return from his first furlough he told of having ridden horseback over his ranch, bought several hundred

head of cattle and of straightening out his business affairs. He wasn't sure he could ride a horse with a prosthesis but he had demonstrated he could ride well without it and was not much concerned about the future.

Patient X had been a successful business man but owing to marital problems he gave up his work and became a heavy drinker. He enlisted to "cure" himself of his drinking. After his return home, as a casualty, he and his wife became reconciled and he had plans to work at a good job for another company. While he was still in the hospital the marital problem flared up and the patient is again drinking heavily.

show more reaction than the older men, and the single more trouble in social adjustment [4] than the married men. Forty per cent of the patients had some notable difficulty in social adjustment (tables 10, 11 and 12).

About one half of these soldiers plan a change in occupation because of the injury (tables 13 and 14). The double amputation and lower limb amputation patients have a greater tendency to plan changes in occupation than those who have lost an upper extremity. Most give rapid tiring and inability to be on their feet

We have attempted to group the reactions to injury in several categories in an effort to explain some of these observations. These categories are represented in tables 10 to 26.

The patients with amputations involving the lower extremities had more difficulty in readjusting to social life with their families, fellows and others than those with upper extremity loss. This is contrary to the report of McKeever and our own expectations, because leg prostheses are less disfiguring and produce less occupational difficulty. In general the younger group for long at a time as the reason for the planned change. Many have rather ambitious plans; for example, a butcher planned to go into personnel work on the basis that his prewar handling of female customers qualified him for this type of work. The younger group, not well established in a job prior to induction, planned a change in occupation in greatest proportion.

4. The term "social adjustment" in this paper is used to designate embarrassment in front of family and friends, reluctance to attend social functions and difficulty in adjusting to fellow soldiers or to physicians and nurses.

The factor of sexual adjustment in relation to the injury is a complex one (tables 15 and 16). We feel that this phase requires longer and more detailed investigation. Deutsch [5] has made observations on surgical patients that may have an important bearing on these patients. The Rorschach picture shows definite signs of sex conflict in 81 per cent of these patients (table 7). Clinically only 30 per cent admit any great concern over the sex function. The married group tend to have less concern than the single soldiers. About one fourth of the single battle casualty group have definite plans to marry, usually immediately after discharge.

Personality change [6] of some definite degree occurred in 62 per cent of the patients (tables 17, 18 and 19). The battle casualties with lower extremity loss show a greater incidence of personality change than those with arm amputation, yet in the accident cases the reverse relationship is found. Double injuries show the highest incidence of change in both groups. In general the older patients show a greater tendency to personality alteration than the younger group, but the trend is not pronounced. Marital status has an inconstant relationship to personality change in this group.

Anxiety is a common symptom, as shown in both Rorschach (67 per cent) and clinical studies (65 per cent) (table 20). The anxiety reaction is slightly more common in the intermediate than in the immediate stages of the patients reaction.

Neuropsychiatric traits [7] other than the aforementioned occur in about 64 per cent of the patients (tables 21 and 22).

Increased use of alcohol is admitted in 11 per cent of the patients (table 23). The increase is greatest in the single patients and tends to be greater in the older age group.

Thirty-eight per cent of the battle casualty patients and 20 per cent of the nonbattle casualty cases admit of increased religious feelings (table 24).

Absence without official leave offenses (table 25) are less common in all groups after injury than before. This is in part due to decreased mobility but mostly due to the high morale of the ward and the liberal furlough policy toward patients in condition to go on leave.

Accident habit was not encountered in these military patients (table 26). Five (6 per cent) of the battle casualties and 1 (4 per cent) of the nonbattle casualties had accidents of some type earlier in their life. This

5. Deutsch, Helene: Some Psychoanalytic Observations in Surgery, Psychosom. Med. 4:105 (Jan.) 1942.

6. "Personality change" in this paper is used to describe changes in habits and general behavior or changes in fundamental attitudes toward the world in general, the family or the Army.

7. "Neuropsychiatric traits" in this paper is used to describe pronounced irritability, sleep walking, battle dreams and so forth (table 22) which persist more than thirty days.

is much below the incidence in the fracture series reported by Dunbar,[8] in which patients in the age group 25-34 years had an incidence of previous injuries of 68 per cent.

No correlation could be made between either educational status or length of military service and the reaction to the injury.

The late reaction comes when these patients return to their homes and attempt to resume their normal place in life. We have formulated plans for following these patients after they leave the hospital. This will depend on the patients' voluntary cooperation, but we hope to be successful in this project. We have had the opportunity to discuss the reaction to amputation with two men injured in World War I. These two men have double amputations, one of the lower extremities and the other of an upper extremity. The National Office of the American Legion has them visiting the various amputee centers as morale builders and to demonstrate what can be done with their prostheses. We frequently see these men and find that they are a big factor in the morale of our patients. During the entire period since their injuries they have both had phantom sensations with cramps, aching and so forth, but they regard them as annoying physiologic experiences and not as evidence of invalidism or disability.

The correlation between the present reaction and the type of adjustment in the future should be the most valuable portion of the study.

COMMENT

The most striking feature of the present study is the high incidence of psychopathologic conditions in a group of persons who seem well adjusted to their immediate environment. The environment to which they are adjusting has certain features that probably aid in this adjustment, and these features should be adequately substituted in the home after discharge. One element of the hospital environment is the acceptance of the patient as an ordinary person and not as an invalid, a hero or an object of pity. The nurses, physicians, fellow patients and even the people in the nearby city have become so accustomed to men lacking one or more extremities that the patients are looked on as other average citizens. This fact gives them great reassurance on their leave from the ward and should be a valuable tip to their families and the projected reception committees in their home town. Conn[9] has discussed this phase of the problem very well and mentions the "War 'Amps' of Canada" organization as an effective mental hygiene measure.

A second feature is the attitude of optimism prevalent among the ward personnel and the patients. The occupational training and physical therapy departments do much to foster this attitude. The patients have a ten-

8. Dunbar, Flanders: Psychosomatic Diagnosis, New York, Paul B. Hoeber, Inc.

9. Conn, H. R., in discussion on Symposium on Amputations, J. Bone & Joint Surg. 26: 670 (Oct.) 1944.

dency to set their occupational goals a little high, but the majority accept guidance in the choice of training and work hard at mastering the various technics.

The importance of a stable wife, sweetheart or mother is enormous. Those who visit them and show the normally expected excitement at the reunion and accept the injury as an unfortunate but unimportant incident give a tremendous boost to their morale. The dramatizers, the weepers and the rejecters add further burdens to the soldier who should be protected from such foolish behavior.

Another important feature in the hospital environment is the group morale or social pressure toward attainment of a useful productive role in life. This works subtly but powerfully. For example, only 1 patient in this series had phantom pain. Many entered the ward complaining bitterly of pain, demanding care from the nurses, asking for "hypos" and in general behaving in the same manner as our civilian compensation cases of phantom pain. Within a day or two these requests and complaints disappear. Neither physician nor nurse has said anything, but his fellows have. A day or so of group disapproval, often bluntly expressed, plus the varied constructive activities of the other patients seem to allay the pain and reorient the person toward his problem. It is realized that this particular brand of psychotherapy is not available outside the amputation section of the hospital, but it indicates that families and family physicians should ignore complaints and encourage constructive activity even though they are considered unsympathetic.

It is our opinion that most of these persons can and will adjust well in the communities after discharge if the community can meet their needs. These needs would seem to be a chance to work productively, marry and be accepted as an ordinary human being. We believe that an opportunity for a discussion of their problems with a competent psychiatrist would aid all patients with amputation to a better and more complete adjustment. This psychiatric aid should be available both in the hospital and after they return home.

SUMMARY

The reaction to the loss of one or more limbs has been studied in 100 soldiers who are considered normal. Seventy-six of these men were injured in battle and 24 in accidents.

Lower limb amputations predominate.

The average age of these patients is 26.7 years.

They are all well trained and experienced soldiers.

In general those with upper extremity injuries, married men and older men have less trouble in social adjustment to amputation.

More than 50 per cent plan some change in occupation as a result of the injury. The planned changes are more common in younger troops and in troops with lower extremity loss.

There is considerable difficulty in sexual adjustment. This phase of the problem is to be investigated further.

Signs of psychopathology in terms of personality change, anxiety, emotional instability, battle dreams and alcoholism occur in a surprising percentage of these men.

Phantom sensations of some type occur in 95 per cent of these patients.

An increased religious feeling is common in the two groups of patients but is more frequent in the battle casualties (38 per cent) than in the nonbattle casualties (20 per cent).

A history of previous accident is not common in these cases.

PHILADELPHIA

In cases of neurosyphilis the response of the spinal fluid and blood are important objective criteria. Herein are suminarized the observations on blood and spinal fluid of 89 cases of neurosyphilis treated from November 1943 to October 1944. This study continues work previously reported [1] but is confined to cases treated at the University of Pennsylvania.

TABLE 1.—*Effect of Penicillin in Neurosyphilis*

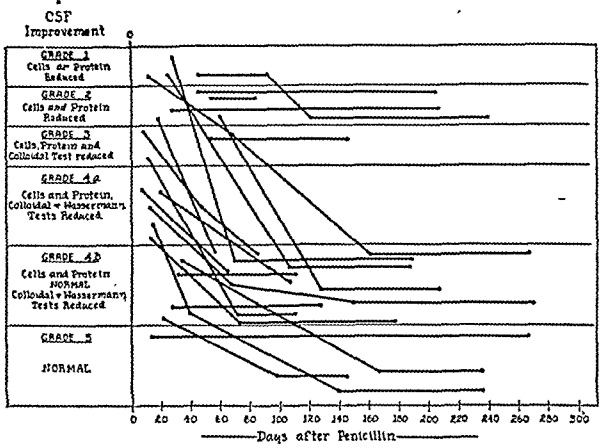
Results in per Cent

		Became Normal	Total Improved	Unchanged	Worse
First course, 89 cases	Spinal fluid	12	72	18	10
	Blood	8	27	70	3
Second course, 29 cases	Spinal fluid	24	41	52	7
	Blood	0	7	83	10

Repeated examination, usually at two month intervals, were made of symptoms and signs and of the blood and spinal fluids. Cell counts were made immediately on fluid withdrawal; total protein was determined by the sulfosalicylic acid method of Kingsbury Clark. Kolmer quantitative Wassermann tests and colloidal mastic tests were run. The serologic tests on the blood were examined by a uniform series of technics, Kolmer, Eagle and Kline; for this report only the Kline quantitative titer results were used.

Sodium penicillin in aqueous solution was given intramuscularly for eight days, every four or three hours, for a total dose of 1.2 or 2.4 million Oxford units; a few received 3.0 or 4.0 million units. There was no intentional uniformity of lot or manufacturer. No other treatment which could influence the results was given.

The work described in this paper was done under contract recommended by the Committee on Medical Research between the Office of Scientific Research and Development and the University of Pennsylvania (OEMcmr-403).



All material of this report is based on contributions from the Hospital of the University of Pennsylvania, Philadelphia General Hospital, Pennsylvania Hospital, Children's Hospital of Philadelphia and individual special departments constituting a penicillin panel.

From the Institute for the Control of Syphilis, University of Pennsylvania, United States Public Health Service cooperating. Neurologic work supported in part by the Kirby-McCarthy Fund.

W.; Morgan, H. G.; Gammon, G. D.; Steele, W.; Rose, E. K., and Gyorgy, P.: Penicillin in Late Syphilis: An Interim Report, Am. J. Syph., Gonor. & Ven. Dis. **29**: 313 (May) 1945.

RESULTS

Penicillin improves the spinal fluid in all its elements and to a lesser degree the blood serologic tests (table 1). The effect on spinal fluid cells and protein is greatest; only 6 of the whole group failed to become normal in respect to these items.

Improvement in cerebrospinal fluid (grades 2 and 3) under penicillin. Results of one course of penicillin. All fluids were, before treatment, grade 2 or 3 in the usual classification. Dots indicate the time of observation and are connected by lines to indicate the curve of the individual case. The improvement begins promptly and continues up to about one hundred and twenty days. The apparent exceptions occur in those cases in which infrequent observations were made. The degree of improvement is considerable in most cases. Retreatment accounts for the short time some of the cases were followed.

Tabetic cases show the least improvement in blood and spinal fluid of the various types of neurosyphilis (table 2). The reason probably lies in the fact that the more abnormal spinal fluids show the greatest improvement, as shown in table 3; the character of the fluid rather than the clinical type of the case appears to determine the response.

In judging the effect of treatment it is important to learn the time course of the change and particularly how long after a treatment session the improvement continues. As shown in the chart, the spinal fluid change begins a few days after penicillin is started and continues up to four months, after which very little further alteration can be seen. To observe the full effect, therefore, the case must be followed at least one hundred and twenty days.

TABLE 2.—*Response of Spinal Fluid of Various Types of Neurosyphilis to One Course of Penicillin*

Type of Neurosyphilis	Cases	Spinal Fluid Response in per Cent: To Normal	Improved	Total Improved	Total Unimproved	Unchanged	Worse	Normal Unchanged
Total.....	89	12	60	72	21	18	10	7
Dementia paralytica.	17	0	88	88	12	6	6	0
Tabes.....	32	16	43	59	32	25	16	9
Meningovascular...	23	19	57	76	19	19	5	5
Asymptomatic.....	11	15	62	77	23	8	15	0
Congenital	6	17	50	67	0	33	0	33

The table shows that the fluids of tabetic patients are least affected by penicillin.

The column Total Unimproved is the sum of columns Unchanged and Worse less column Normal, Unchanged. The sum of columns Total Improved, Total Unimproved and Normal Unchanged equals 100. Column Unchanged includes Normal Unchanged group; therefore the sum of Total Improved, Unchanged and Worse equals 100.

Two dosage levels were used: a low dose of 1.2 million units and a high dose of 2.4 million; a few patients were given 3.0 and 4.0 million units. Comparison of the results in these two groups appears to show no difference between them (table 4). But if the time element is taken into account, that is, if the cases

TABLE 3.—*Spinal Fluid Response in per Cent to One Course of Penicillin*

Control Spinal Fluid	Became Normal	Total Improved	Unchanged	Worse
Severely abnormal, 56 cases.....	13	93	2	5
Moderately abnormal, 23 cases....	17	51	40	9
Normal, 10 cases.....	..	..	60	40

Control spinal fluid signifies pretreatment fluid. The severely abnormal fluids are grade 3 in the usual classification. Moderately abnormal includes fluids with normal cells and protein but abnormal Wassermann and mastic curves.

The more abnormal fluids show a greater response than the less abnormal fluids. This is due in part to the fall in cells and protein, which almost always improve. Normal cases becoming worse usually show a very mild abnormality, which may be within the error of the methods used.

are followed long enough to obtain the maximum effect, there appears to be a slightly better response in the higher dosage group (table 5). In this table patients given one course only at low and at high dosage are compared with the final result in patients given a high dose administered in two courses, in other words, retreated. From the last three columns of the table it can be seen that better results are obtained from a high dose than a low one, and the best results from a high dose given in two courses as retreatment. In the latter, the effect of time is operative as well as dosage. It therefore appears that giving the high dose over a longer time is more effectual than administering it in a single short course. Although when tested by the chi square there is not a significant difference between these groups, the trend to the foregoing conclusion is clear.[2]

In view of these considerations and in order to judge the effect of time or length of treatment as well as the dosage levels, it is believed desirable to plan further treatment of neurosyphilis along these lines: Total

TABLE 4.—*Comparison of Effect of Various Amounts of Penicillin on Spinal Fluid and Blood (in Parentheses), One Course*

Results in per Cent

Million Units	Cases	To Normal	Total Improved	Unchanged	Worse	Control Normal No Change
1.2	54	13 (9)	68 (28)	19 (61)	9 (2)	4 (9)
2.4	22	8 (6)	72 (24)	6 (47)	11 (6)	11 (23)
3.0	7					
4.0	6					
	35					

No significant difference between the results of a low dose of 1.2 million units and a high dose can be seen. This table differs from table 5 in that the length of time after treatment is not considered.

dosage should be kept constant; it should be administered (1) as a single course and (2) split into two courses, the second given (*a*) at the end of the first course and (*b*) later, probably at the time when the results of the first have leveled off, at one hundred and twenty days.

Considering the data now available, we are increasing the total dose to 4.8 million units; this may be given in a single course of eight days and split into 2.4 million units administered in two courses at different times, as described.

The observation period over which these cases were followed is, in days, less than thirty, 1 per cent; thirty to sixty, 5 per cent; sixty to one hundred, 12 per cent; one hundred to two hundred, 31 per cent; two hundred to three hundred, 35 per cent; three hundred to four hundred, 14 per cent; to four hundred and eighty-three, 1 per cent.

SUMMARY

Penicillin shows a clear effect on the blood serologic reactions in neurosyphilis and an even greater effect on the elements of the spinal fluid. Fluids showing the greatest abnormality improve most. The improvement apparently continues for as long as four months after an eight day course.

Both dosage and length of treatment are important in the result. Within the amounts of sodium penicillin employed in this study, a larger dose is better than a smaller and the best results are obtained when the larger dose is given in two courses; that is, when the length of treatment is increased. In view of the history of other forms of treatment for syphilis, this might have been expected.

TABLE 5.—*Effect of Various Dosages of Penicillin on Spinal Fluid*

Dose in Million Units	Cases	Normal	Improved	Unimproved
One course, 1.2; 2.4; 3.0; 4.0....	41	22	80	20
One course, 1.2.....	24	21	75	25
One course, 2.4; 3.0; 4.0.....	17	24	88	12
Two courses, 2.4; 3.0; 4.0.....	20	31	92	8

The time of each course was the same, eight days. One course signifies no further treatment; all of these were followed one hundred and twenty days or more, which is long enough to observe the maximum change (as shown in the chart). Fluids normal before and unchanged during treatment are deleted.

A better result is obtained from a high dose than from a low dose, and the best result from a high dose given in two parts. Increasing the length of treatment as well as the dose improves the results.

2. Dr. Harold Austin gave advice on statistical matters in the study.

First Great Name in American Science.—Though his career as a printer, publisher, almanac keeper, diplomat, statesman, signer of the Declaration of Independence and member of the Constitutional Convention—not to mention his exploit with the kite, the key and the lightning bolt—are well known, too few, perhaps, appreciate that "Poor Richard," Benjamin Franklin, is the first great name in American science. Among his significant scientific contributions, most of which preceded his diplomatic days, can be named invention of the "Franklin stove" and bifocal spectacles; founding of hospitals, libraries and the first American scientific society, the American Philosophical Society (1743); improvement in public works, such as street lighting and postal systems; description of lead poisoning, an industrial disease of the print shop; and experiments in electricity. Franklin's famous kite experiment, performed in June 1752 in Philadelphia, was undertaken to prove that lightning, fashioned in the skies of the gods of the weather, was the same stuff that men were making on earth with their newly invented "static electricity machines" and storing in "Mr. Muschenbrock's wonderful bottle," the foil lined Leyden jar out of Holland. Franklin had completely investigated this "shocking instrument" a year or two after its invention (1745) and had concluded that there were two kinds of electricity, which he named positive and negative. Franklin was not the only founding father of the Republic who was interested in science. When Thomas Jefferson (1743-1826), author of the Declaration of Independence, rode horseback to his inauguration as third President of the United States in 1801, he carried in his saddlebags specimens of fossil bones on which to lecture before the American Philosophical Society.—The Autobiography of Science, edited by Forest Ray Moulton and Justus J. Schifferes, New York, Doubleday, Doran & Co., Inc., 1945.

THE USE OF DRUGS IN RESUSCITATION FROM ELECTRIC SHOCK

CECIL K. DRINKER, M.D.
BOSTON

For many years I have encountered the apparently irresistible compulsion of doctors to give some sort of hypodermic injection to patients overcome by carbon monoxide, close to death from submersion, or in desperate straits from electric shock. At one time in a long experience I listed, as well as the records permitted, the different drugs given in carbon monoxide emergencies by ambulance physicians in New York. Nothing in the traditional teaching of medical students was left out.

This is not such a reflection on these young doctors and their training as may be thought. The drugs injected can be shown to stimulate breathing but not in the dosage or under the circumstances which are of consequence in the emergencies in which we are interested.

Let us consider an instance of electric shock in which the victim, who is obviously unable to breathe and whose heart and circulation may or may not be operating, is being given artificial respiration. The questions which arise at such a juncture are whether any drug can be administered which will at once improve the chances for reviving the breathing or aid the condition of the circulation.

STIMULANTS TO BREATHING

The following drugs can be shown by animal experimentation to stimulate breathing. I shall list what they do and where they fail. All the drugs can be given intravenously or under the skin by injection.

1. *Strychnine Sulfate.*—This alkaloid has a stimulating action on the spinal cord, on the medulla containing the respiratory center and on the brain. But in dosage of nonpoisonous size, strychnine has no appreciable effect on breathing and, when given in sufficient amount to stimulate breathing momentarily, the drug is eventually depressing to respiration and thus adds to, rather than remedies, the condition of the patient. The fact is that all medical men have so wholesome a respect for strychnine as a poison that such injections as are frequently given are so small as to be both ineffectual and harmless.

2. *Picrotoxin.*—This drug is a strong stimulant to the nervous system, particularly the lower brain and medulla, where respiration originates.

Again, however, it has been shown that when enough picrotoxin is injected to stimulate breathing convulsions result.

Picrotoxin, used carefully, under hospital conditions has proved useful in combating poisoning due to the barbiturates (veronal and other barbituric acid derivatives) but has no place in emergency failure of breathing from electric shock.

3. *Metrazol.*—This drug is related to camphor and has had extensive use in the treatment of certain sorts of insanity by the production of generalized convulsions. This means it is a strong stimulant of the nervous system, but it has no conspicuous effect on breathing and has no value in respiratory failure from electric shock.

4. *Nikethamide* (Coramine).—This is a relatively new drug and has some promise as a stimulant of a depressed breathing center. This value is, however, very uncertain, and nothing so far claimed for it makes the compound worth serious consideration in electric shock therapy.

5. *Caffeine and Sodium Benzoate.*—This caffeine compound is suitable for intravenous injection, and caffeine even in enormous dosage seems devoid of harmful effects of a serious sort. There is no doubt of the general stimulating effect of caffeine on the central nervous system, the breathing center included. I think it fair to describe the action as a sort of oiling of staggering nerve machinery. It thus makes normal processes in the breathing center go on more readily, and I know of no evidence that the drug can or has done harm. An intravenous injection of caffeine and sodium benzoate is not out of place in any sort of respiratory depression, but the injection must be made directly into the blood by vein and not be a simple hypodermic (under the skin), since prompt action is imperative.

6. *Alpha Lobeline.*—This drug had popularity as a respiratory stimulant about ten years ago and, fortunately, has dropped out of use, owing to its very capricious effect as a stimulant to breathing and its emphatically disadvantageous effects on the heart and circulation.

SUMMARY

At the present time there is no substance which can be given by injection which benefits the breathing significantly. Caffeine and sodium benzoate intravenously may be useful but has no specific potency.

In my opinion the Edison Institute might do well to consider financing research looking toward the discovery of some substance which will be of substantial aid to the respiratory center, much as does caffeine, but really efficient. I do not think any agency so completely dependent on the attendance of a physician, as is an intravenous injection, can be of primary consequence in resuscitation from electric shock, but year by year we have instances of artificial respiration carried out for minutes to even many hours with eventual recovery. It must be clear to every one that the most our crews trained in artificial respiration accomplish during their period of effort is to substitute artificial breathing for absent natural breathing. They merely give the patient a chance to recover by arresting asphyxia. I believe more than this could be done in the direction of finding some direct aid to the respiratory center and that in such a direction we shall see our greatest advances in the resuscitation of the most serious electric accidents.

STIMULANTS TO THE HEART AND CIRCULATION

The condition of the heart and the blood circulation as a result of electric shock is far better understood than was the case even a few years ago. Divested of all the medical description possible, it seems to me that the following circulatory derangements may be met:

1. The shock, by passing through the medulla, may have stopped the breathing and left the circulation of the blood somewhat impaired but not seriously so. This

From the Department of Physiology, Harvard School of Public Health. Read before the Committee on Safety of the American Institute of Electrical Engineers, New York, Jan. 23, 1945

is the ideal case for resuscitation. But if four or five minutes of absent breathing intervene before artificial respiration is started, the heart and blood vessels will begin to show the effects of oxygen lack. Oxygen will remedy this condition, and no injection or treatment other than artificial respiration is required or advisable.

2. The medulla, in addition to the breathing center, contains in very small space the centers for regulating the heart rate, particularly for slowing the heart and for regulating the blood pressure by controlling the caliber of the smallest blood vessels One may thus expect that a shock which stops breathing can readily affect nearby units concerned with the circulation. This occurs and, consequently, the situations resulting may be quite varied. Let me list a few of them:

(*a*) Breathing may be absent and the heart very slow and weak with low blood pressure.

(*b*) Breathing may be present, the heart slow and the blood pressure variable but becoming low

(*c*) Breathing may be irregular with a tendency to stop, the heart slow, irregular and weak, and the blood pressure low.

Obviously, these possible situations may vary between themselves so that in each case the condition of the circulation can be appraised only by a competent physician. By "competence" I mean a man capable in cardiology and with at least some knowledge of the consequences of electric shock Very few doctors meet this last mentioned requirement, and consequently the treatment given such patients is not, to say the least, discerning

Artificial respiration for absent or inadequate breathing is, of course, essential, since lack of oxygen will make the condition of the circulation grow worse rapidly. If breathing is feeble and unreliable, oxygen-carbon dioxide inhalation is helpful Absolute rest is imperative.

If the blood pressure continues to remain low and the heart feeble so that the patient begins to be in danger for circulatory inadequacy, the physician may consider giving an intravenous injection of a small dose of epinephrine or ephedrine. In either case the injection should be given very slowly and should be understood to be a last resort. Caffeine and sodium benzoate, discussed in the section on breathing, should have been given early in the management of the case and will benefit the circulation.

3. The shock by passing through the heart may cause ventricular fibrillation The patient is dead white, not bluish. No pulse can be felt and after three or four breaths respiration ceases. Such patients are often given injections of epinephrine through the chest wall directly into the heart

There is increasing evidence that ventricular fibrillation occurring spontaneously in man, though usually fatal, occasionally ceases with return of the heart to normal rhythmic beating. There is no reason to believe the same thing may not happen *after electric shock*, but such an event must be very rare.

There is no practical procedure which affects the fibrillating heart muscle, and an intracardiac injection of epinephrine can be relied on to do but one thing, namely make fibrillation worse, *so that any chance of* spontaneous shift to normal pulsation is lost.

Clinical Notes, Suggestions and New Instruments

SKIN GRAFTING IN HEMOPHILIA WITH A PREPARATION OF THROMBIN AND SULFANILAMIDE

CHARLES S DAVIDSON, M D, AND STANLEY M LEVENSON, M D
BOSTON

Operative procedures on patients with hemophilia are not often undertaken because of the high postoperative mortality Excessive bleeding following such a simple operation as tooth extraction has been a common cause of death[1] Recently the use of certain active thrombin preparations has made tooth extraction in hemophilia a relatively safe procedure[2] To our knowledge skin grafting has not been attempted in hemophilia, largely because of the likelihood of uncontrolled bleeding from the donor site

Fig 1.—Recipient area before skin grafting

The present report concerns a successful skin graft operation on a patient with hemophilia by means of a preparation of thrombin[3] and sulfanilamide[4] to control the bleeding from the donor site

REPORT OF CASE

W. M., a white man aged 26, hemophilic, of Irish descent, was admitted for the fourteenth time on March 6, 1944

His previous admissions had been for bleeding from a cut lip, from the buccal mucosa, for epistaxes, for hematomas for bleeding from loss of "milk" teeth and from cuts on the right

From the Thorndike Memorial Laboratory; the Second and Fourth (Harvard) Medical Services, Boston City Hospital, and the Department of Medicine, Harvard Medical School

The expenses of this investigation were defrayed in part by a grant given "In recognition of Dr Francis W. Peabody's Services to the Foundation" by the Ella Sachs Plotz Foundation

knee. He also suffered, from the age of 2, from other episodes of abnormal bleeding, especially hemarthroses and attacks of hematuria. The coagulation time of his blood has been from one to one and one-half hours as measured by a modification [5] of the method of Lee and White [6]

Fig 2.—Donor site at operation after application of thrombin with sulfanilamide. Note absence of bleeding.

The patient's family history included one maternal uncle, one brother and one maternal first cousin and one second cousin with hemophilia.

Fig 3.—Recipient area nine months after grafting. Complete healing.

The present bleeding episode began one month before admission following an abrasion and contusion of the right leg just distal to the anterior tibial tubercle. A transfusion of whole blood was given and a dry sterile dressing applied to the area. There was little subcutaneous hemorrhage. Healing was satisfactory, but the area was traumatized again three and one-half weeks later and became swollen, red and exquisitely tender. There was an area of cellulitis extending from the knee to the ankle, and swollen tender lymph nodes appeared in the right groin. His temperature was 102 F., the pulse rate 140. The following day the wound began discharging old blood and pus, and the patient was admitted to the hospital. Full doses of sulfadiazine orally were begun, and débridement of the gangrenous skin over the infected hematoma was carried out, care being taken not to incise normal skin. A considerable amount of pus and large blood clots were removed. A firm dressing of a sulfathiazole emulsion [7] was applied and subsequently changed infrequently. The patient became afrebrile on the fourth day and remained so thereafter. The cellulitis subsided and the wound began to granulate. Two weeks after admission, under pentothal anesthesia, a split thickness razor graft was taken from the lateral aspect of the left thigh and applied to the granulating area (fig. 1). The bleeding from the donor site was controlled instantly by applying a mixture of powdered sulfanilamide and thrombin to the area (fig. 2). Firm dry dressings were applied to both donor and recipient sites. There were no postoperative complications. The donor site healed uneventfully in nine days. The take of the graft was excellent (fig. 3).

THROMBOCYTOPENIC PURPURA DUE TO MAPHARSEN (OXOPHENARSINE HYDROCHLORIDE U. S. P.)

MARVIN SCHWARTZ, M.D., AND ELMORE C. VONDERHEIDE, M.D.
DETROIT

Blood dyscrasias such as thrombocytopenic purpura are uncommon complications of arsenotherapy for syphilis. It was nine years after the introduction of arsphenamine before Labbé and Langlois [1] called attention to the fact that purpuric manifestations might be a complication of this therapy for syphilis.

Loveman [2] was able to find reports of 14 instances of purpura hemorrhagica following arsphenamine therapy up to 1931 and added 1 case of his own. In 1942 Engelhardt,[3] in reporting a case of purpura hemorrhagica following neoarsphenamine, found 50 cases of thrombopenic purpura complicating arsphenamine therapy. Falconer and Epstein,[4] in discussing their observations on 8 cases of typical purpura following arsphenamine, have expressed the opinion that this toxic manifestation of arsphenamine therapy was relatively more frequent than reported and that the increased number of reported cases was probably due to a more widespread interest and alertness in recognition of complications due to arsphenamine therapy.

Neoarsphenamine, arsphenamine, sulfarsphenamine and bismarsen have been the arsenicals most frequently associated with this complication. Of this group neoarsphenamine has been by far the most often linked with this complication. However, one should not infer from this fact that neoarsphenamine is the most toxic of the arsenicals, since the latter drug up until recent times has been the most commonly employed of this group of arsenicals in antisyphilitic therapy. Mapharsen was introduced in 1936 for general use and has been used extensively since that time in the treatment of syphilis. Review

of published reports fails to reveal a single instance of thrombopenic purpura complicating mapharsen therapy. However, Wintrobe[5] has recently stated that he has seen 3 instances of this complication due to the drug. It is our purpose in this paper to report a case of thrombopenic purpura complicating mapharsen therapy for syphilis.

REPORT OF CASE

A white man aged 24, admitted to Detroit Receiving Hospital Nov. 16, 1941 because of copious bleeding from his mouth and nose, on admission gave a history of a penile lesion in March 1941 followed by a generalized eruption a month later. His family physician found a positive serologic reaction and instituted antisyphilitic therapy on April 24. This consisted of 0.06 Gm. of mapharsen intravenously and a bismuth compound intramuscularly for thirty weeks without a rest period. The first seventeen injections were well tolerated. Shortly after each of the last thirteen injections he experienced transient severe headaches. However, there were no other untoward symptoms.

On November 14, two days before admission to the hospital, he received his thirtieth injection of mapharsen. This was soon followed by severe headache, nausea and vomiting. Later that day he began to bleed from the mouth and subsequently from the nose. Local measures were of no value in controlling the bleeding. The next day a purpuric eruption was noted over the lower extremities and at the same time he noted that he bruised very easily and ecchymotic areas appeared over the upper arms.

There was no history of allergic, familial or hereditary disease. No drugs other than bismuth compounds and mapharsen were taken during his course of antisyphilitic therapy. Although isolated reports have appeared implicating bismuth,[6] it seems unlikely that this was the offending drug in this case, since bismuth was reinstituted after his recovery without untoward effects.

Physical examination on admission revealed that the patient was well nourished and developed and was acutely ill. The blood pressure was 124/70 and his temperature was elevated to 101 F. There was a purpuric area in the right conjunctiva, and a few small flame shaped hemorrhages were seen in both fundi. The mouth was foul smelling, and over the soft palate and posterior pharynx there was a large ecchymotic area. The uvula was edematous and ecchymotic, and there were several blood filled blebs on the buccal mucous membranes. Although he had profuse epistaxis, no bleeding points were discernible. There was no adenopathy, and but for a soft systolic murmur at the apex the heart and lungs were normal. The liver edge was palpable at the right costal margin and the spleen descended 2 fingerbreadths below the left costal margin. Over both tibial areas of the legs there was a generalized purpuric eruption. The capillary fragility test at this time was strongly positive.

Shortly after admission a blood count revealed 11.5 Gm. of hemoglobin, 4,160,000 red blood cells and 9,300 white blood cells, with 95 per cent neutrophils and 9,320 platelets. The bleeding time was over fifteen minutes and the clotting time eleven minutes. There was no clot retraction in twenty-four hours. Urinalysis was negative; the Kline reaction was doubtful but the Kahn reaction negative.

He received a 500 cc. blood transfusion the day after admission, but he continued to bleed from the mouth and nose for another two days. Daily platelet counts during this time varied between 4,000 and 6,000 platelets. In addition there appeared a fall in hemoglobin and erythrocytes as the result of continued bleeding. From the fifth day after admission until he was discharged from the hospital the platelet count rose, with the subsidence of bleeding manifestations and disappearance of the purpuric eruption. The spleen decreased in size during this period, being barely palpable three weeks after admission. A bone marrow aspiration on November 25 was entirely normal; the megakaryocytes present appeared of normal structure, staining quality and number. The bleeding time returned to within normal limits nine days after admission, at which time the clot retraction was complete in two hours and the capillary fragility test was negative.

Before he was discharged he received 5 mg. of mapharsen intravenously and its effect on the blood platelets was noted by taking platelet counts before and one-half hour after the injection. This amount of mapharsen had little effect on the blood platelets, the count being 194,000 before and 154,000 one-half hour after the injection. However, the patient complained of severe headache shortly after this procedure, there was an accompanying increase in pulse rate and the blood pressure, which had on former occasions averaged 120/80, fell to 96/60. The effects were of only short duration and resembled a nitritoid reaction.

On Dec. 9, 1941 he returned to the outpatient department and at this time received 40 mg. of neoarsphenamine intravenously so that its effect on the thrombocytes might be studied. It is well to remember that although this dose is a comparable fraction of the therapeutic dose it actually contains 8 mg. of arsenic, whereas the mapharsen test dose contained only 1.5 mg. of arsenic. A platelet count done before the injection of neoarsphenamine revealed 184,000 platelets. However, one-half hour after the injection the platelet count had fallen to 1,800. Somewhat later in the day he again began to bleed from the nose and mouth and hospitalization was again necessary. Physical examination on this admission revealed oozing from the gums and nose and hemorrhagic herpetic lesions on the mucous membranes of the lips. There was some oozing from the site of the intravenous injection, and over the ankles and tibias a purpuric eruption again appeared. The day after admission no platelets were found on examination of the peripheral blood, bleeding time was again prolonged, there was no clot retraction in twenty-four hours and the capillary fragility test was positive. From this time until his discharge from the hospital three days later the platelets rapidly rose to normal levels, the oozing from the mucous membranes of the mouth and nose subsided and the purpuric eruption disappeared. Blood studies done on this admission revealed a slight posthemorrhagic anemia but no abnormalities of the leukocytes.

He was treated with weekly injections of bismuth following his discharge with no untoward effects. After five months there was a reversal of his serologic reaction to negative and he was subsequently inducted into the armed forces.

COMMENT

In view of this thrombopenic reaction to mapharsen it is interesting to note the work done by Falconer and Epstein.[7] They studied several cases of thrombopenic purpura that were due to sensitivity to neoarsphenamine and bismarsen and administered as much as 40 mg. of mapharsen without effects on the platelets and capillaries and without observing constitutional manifestations. These investigators thought that the quantity of arsenic may be an important factor for this phenomenon, since mapharsen contains less arsenic. This seems to be borne out, at least in this case. Although sensitization to neoarsphenamine had resulted from the long administration of mapharsen, the reaction to a therapeutically equivalent dose of neoarsphenamine was much greater than that following a test dose of mapharsen. It was also suggested by Falconer and Epstein in view of the lack of reaction to mapharsen in their neoarsphenamine sensitive cases that sensitivity may be due to some oxidation product not present in mapharsen. The latter thought, however, does not seem plausible in view of this reported case of thrombopenic purpura due to mapharsen. Because of the differences of reaction in this case to comparable test doses of mapharsen and neoarsphenamine, it would seem that the factor of quantitative differences of arsenic present in neoarsphenamine and mapharsen might be the more important one. Further treatment with mapharsen of patients already

6. Bianchi, A. E.: Comments on a Case of Purpura, Rev. Asoc. méd. argent. 46: 1566 (Dec.) 1932.

7. Falconer, E. H.; Epstein, N. N., and Wever, G. K.: Purpura Hemorrhagica Following Administration of Neoarsphenamine, Arch. Int. Med. 58: 495-511 (Sept.) 1936. Falconer and Epstein.[4] Epstein and Falconer.[8]

sensitized to one of the other arsenicals may be extremely hazardous even though it was found that mapharsen produced no ill effects on the blood platelets of patients having had thrombopenic reactions to neoarsphenamine, bismarsen and other arsenicals.[8]

The exact mechanism for this purely thrombopenic reaction to the arsphenamines is not clearly understood. All these reactions are characterized by three findings: (1) free bleeding from mucous membranes, (2) a very rapid fall in circulating thrombocytes, as rapidly as fifteen to thirty minutes following the injection of an arsenical, and (3) evidence of increased capillary fragility as manifested by purpuric spots and a positive Rumple-Leede test. In this case, as well as in others so studied, the bone marrow showed no abnormalities. It is also noteworthy that a great number of platelets can be returned promptly into the general circulation by the injection of epinephrine,[4] although the latter observation was not found to be true in the case herein reported. In most cases of thrombopenic purpura following arsenotherapy the platelet count begins to rise in twenty-four to forty-eight hours and returns to normal in four to seven days after the reaction, as was true in this case. No fatalities have been recorded thus far as a result of this complication, differing in this respect from the other types of blood dyscrasia reactions to the arsphenamines.

It would seem, therefore, that the blood platelets that disappear from the circulation are not actually destroyed and that there has not been selective destruction of the megakaryocytes in the bone marrow. Falconer and Epstein[8] have postulated the theory that the blood platelets leave the larger vessels and enter greatly dilated capillaries, which are more permeable, probably because of some toxic action on the vasomotor center controlling capillary tonus. These investigators[9] have studied the effects of neoarsphenamine on the formed elements of the blood and have found no conclusive evidence that it affects the platelets to any extent. On the other hand, Mu[9] has observed a significant fall in platelets following the intravenous administration of neoarsphenamine. However, it should be noted that he was using doses which were much greater than those ordinarily employed therapeutically in the treatment for syphilis. It would seem, therefore, that thrombopenic reaction to the arsphenamines is due to the development of a sensitivity to repeated injections of the arsenicals employed and resembles to some extent a nitritoid reaction. It is interesting to note that peripheral thrombocytopenia has been observed in experimentally produced anaphylactic shock.[10]

SUMMARY

1. A case was observed of thrombopenic purpura following the prolonged administration of mapharsen. Although a few other cases of this complication following mapharsen have been seen, we believe this to be the first reported case.

2. Although mapharsen has been used with no untoward effects in some cases of thrombopenic purpura in which sensitization to neoarsphenamine has occurred, nevertheless it may be extremely hazardous to employ any arsenical once a patient has had such a reaction.

3. This thrombopenic reaction to mapharsen has many of the characteristics of a sensitivity reaction and resembles the nitritoid phenomenon.

4. From the available evidence it seems reasonable to assume that the platelets in the peripheral blood are not destroyed but are merely dislocated temporarily into the large capillary beds of the vascular tree, which have been rendered more permeable.

5. Isolated thrombopenic reaction following arsenical therapy is invariably associated with a good prognosis, provided the drug is stopped.

Council on Foods and Nutrition

SPECIAL ARTICLE

This is the ninth and last of a series of articles discussing the significance of protein nutrition in health and disease. This material was prepared by the authors at the request of the Council and has been authorized for publication.

GEORGE K. ANDERSON, M.D., *Secretary.*

THE PRACTICAL USE OF AMINO ACIDS IN PROTEIN NUTRITION

ROBERT ELMAN, M.D.
ST. LOUIS

Amino acids are to protein what glucose is to starch. In other words, they are the unit components of food and tissue protein. Their discovery, purification and identification mark one of the milestones in the development of the science of nutrition. The isolation from foods of these specific chemical components which enter into the metabolic activities of the body represents the most important recent contribution of chemistry to the field of nutrition.

Amino acids differ from vitamins in that they are more than catalysts or enzymes; they actually enter into the structure of body tissue. While they are thus used up like glucose, unlike the latter they are not burned as fuel unless calorigenic elements are absent, when they may act for glucose when the latter is not available. They are also unlike other purified food essentials because there are so many of them. The glucose molecule represents the form in which carbohydrate is utilized; even the vitamin B complex has been divided into a number of different crystalline substances. On the other hand, amino acids are twenty-one or more in number, each different, though conforming to the same general chemical formula in that they contain an amino group and a carboxyl group.

Consideration, therefore, of the amino acids as the structural units of food protein leads immediately to an enumeration of these various amino acids (table 1). Most important is the fact that but ten of them may be considered as "essential." These essential amino acids are also termed indispensable in that the body is unable to manufacture them from other amino acids or from simpler material and that they must be supplied before normal protein metabolism can occur. For example, normal growth will take place if these essential amino acids are fed to growing rats as the sole source of protein in the diet. Yet if one of them is omitted, normal growth is not obtained. In this sense certain of the individual amino acids assume an importance comparable with the vitamins in maintaining normal nutrition and life processes. Much of the recent investigation regarding the nutritive significance of the amino acids has been carried out and described by W. C. Rose.[1]

Further consideration of amino acids reveals the fact that each protein in the body as well as each protein in food has its own individual amino acid composition (table 2). Thus transfers from one protein to another may be conceived as requiring a breakdown of the

protein molecule into its individual amino acids with the reassembling of them to form another protein. This general procedure is the normal method by which food protein is transformed into tissue protein—hydrolysis or digestion occurs in the gastrointestinal tract; the resulting amino acids are absorbed into the portal system and the synthesis of these building stones then takes place in the liver and other tissues. It is also probable that extra-

Methionine	Proline
Valine	Hydroxyproline
Arginine	Tyrosine
	Cystine

alimentary transfers also require a similar mechanism as, for example, the use of tissue protein in the synthesis of new serum protein after its loss in a hemorrhage. Other types of interchange between protein molecules also occur, as shown for example by the recent studies of Schoenheimer.[2] The important conception to emphasize from these new studies on protein metabolism is one of dynamic rather than static equilibrium. In other words, protein is constantly undergoing rapid and perhaps profound changes of many kinds; the concept of great masses of inactive protein stores must be abandoned—all protein tissue is in a constant state of chemical activity.

By using amino acids instead of food protein the physician can administer protein nourishment in its simplest form just as he uses glucose. With parenteral administration he does not have to depend on digestion and absorption by the gastrointestinal tract. In this way protein starvation can be avoided even though these two functions are completely impaired. Even if the patient requires parenteral fluids, these need no longer be confined to salts or glucose; protein building substances can now be just as easily supplied. Amino acids may also be administered orally for the maintenance of proper nutrition in certain special conditions, as will be described

SOURCES OF AMINO ACIDS

Like chemically pure glucose and vitamins, amino acids are available in crystalline form and may be purchased on the open market as such. They may then be combined in the desired proportions and given to the patient either by mouth or by injection just as in the case of crystalline vitamins or glucose. The greatest drawback to this is the cost. The large amount of protein nourishment needed makes the use of crystalline amino acids unpractical at the present time, although it may be that in the future chemical methods will be devised whereby crystalline amino acids may be cheap enough to permit their general use. Another objection to crystalline amino acids is the fact that, in preparing some of them, racemic mixtures are obtained containing both the natural and unnatural isomers, which are difficult to separate. All natural proteins contain only the natural isomers, although in the case of some amino acids the two forms are equally utilized. The suggestion of Albanese [3] that the unnatural form may in some cases be deleterious is an important consideration which needs further investigation.

By means of an adequate digestion in vitro of natural proteins a mixture of amino acids may be easily obtained. These procedures are essentially similar to those by which the body produces amino acids from protein food in the gastrointestinal tract and are both practical and cheap. Such methods of preparing amino acids involve the possibility of losing some of the essential ones during the procedure of digestion and purification. However, losses are dependent on the technical details and moreover can be measured by testing the resultant digest both chemically and biologically for the presence of all the essential amino acids. Another disadvantage of using protein hydrolysates as a source of amino acids is the possible generation or introduction of foreign or deleterious substances during manufacture This difficulty can, apparently, be avoided by carefully conducted procedures. A final possible criticism is the presence of peptides as well as amino acids in the final mixture; this objection appears to be of no practical significance. As long as digestion has been sufficient to remove all traces of true protein molecules, no danger seems to arise from the presence of peptides provided they are not too large. How large they may be is not really known. On the other hand, it may prove advantageous to provide some peptides rather than single amino acids in that one step in the process of building of body protein may be saved.

The several methods for producing amino acids by the digestion of protein may be classified in general into enzymatic and acid hydrolysis methods. Thus far the enzymatic procedure has been the more exten-

These figures were obtained from Block and Bolling (The Amino Acid Composition of Proteins and Foods, Springfield, Ill., Charles C Thomas Publisher, 1945) with the exception of those marked with an asterisk (*), which represent data obtained by the analysis of gamma globulin and crystalline albumin by Brand, Kassell and Saidel, (J Clin Investigation 23: 437, 1944) They represent grams per hundred grams of the dry protein on the basis of 16 per cent nitrogen

Note how deficient gelatin is Note also that serum albumin is deficient in tryptophan and low in isoleucine A deficiency of isoleucine in human plasma protein has been shown by Hegsted, McKibbin and Stare in growth experiments (J Clin Investigation 23: 705, 1944)

sively used and has given very satisfactory results. In a review on nitrogen balance I [4] have reported the successful results obtained with use of a protein digest [5] prepared by pancreatic hydrolysis of casein. This product contains the amino acids of casein and pancreatic tissue, two animal proteins of high biologic value. Although its content of essential amino acids is not accurately known, biologic tests have shown that

it contains all in sufficient concentration to support growth in rats when given as the sole source of nitrogen.[6] This is one of the most rigid tests of the efficiency of protein. Amino acid preparations produced by enzymatic hydrolysis contain approximately 70 per cent of the potential amino acid nitrogen in the form of amino nitrogen (representing amino acids), most of the remainder being present as peptide nitrogen. In the case of acid hydrolysis more nearly 100 per cent of the nitrogen can be obtained in the form of free amino acids, although it is known that the tryptophan is destroyed in the process of acid hydrolysis. This must be replaced in the products prepared by this method. It has now been demonstrated clinically that protein hydrolysates containing amino acids and peptides, when given in adequate amount, can maintain nitrogen balance effectively and cause regeneration of serum proteins.[6a]

GENERAL INDICATIONS FOR THE USE OF AMINO ACIDS

Whenever there is a failure in normal ingestion, digestion and absorption of food protein, inevitable deficiencies in protein begin to develop at once unless protein is supplied in some other way. The proper use of amino acids provides a practical method of preventing protein starvation. Any patient who does not eat will develop a protein deficiency; any patient who eats but does not digest or absorb his food will likewise suffer protein starvation. He may, of course, suffer deficiencies in other elements, water and salts, for example. Just as the universal use of solutions of glucose and saline obviates many of these deficiencies, the wider use of amino acids will prevent deficiencies in protein, which may be just as important as preventing deficiencies of water, electrolyte and vitamins. As far as parenteral administration is concerned, it may be stated as a general proposition that, when solutions of saline or glucose are injected for maintenance of daily needs, amino acids are indicated as well.

Protein deficiencies are actually of frequent occurrence in clinical medicine, yet they are seldom recognized because we as physicians are apt to view an inadequate protein intake with complacency. While we have recognized the importance of supplying glucose and vitamins, water and salts, we have looked on other food (e. g., protein) as being dispensable. We have been lulled into a false sense of security by the supposition that there are large stores of reserve body protein and that the absence of protein intake may result in little or no difficulty. The fallacy of this view is indicated in a recent review[6b] and in the other papers of this series in which the various clinical manifestations of protein deficiency have been described. Of these, a decrease in the level of plasma proteins (hypoproteinemia) is of great importance. However, it may be emphasized that hypoproteinemia, while not always found, is one of the objective evidences of protein deficiency, particularly when there is a fall in the albumin fraction. Though often masked by dehydration and an increase in the globulin fraction, a fall in plasma proteins has been observed frequently, especially after operation. Indeed, hypoproteinemia has now been demonstrated to be frequent in both medical and surgical wards of any hospital.

SPECIFIC INDICATIONS FOR THE CLINICAL USE OF AMINO ACIDS

A. Patients unable to ingest protein because of severe gastrointestinal disease or persistent vomiting from any other cause: In these cases amino acids must obviously be given parenterally. They include such conditions as intestinal obstruction, local or general peritonitis, acute cholecystitis and a severe peptic ulcer in which the ingestion of any food provokes severe pain or vomiting. Important in this group are cases of chronic disease such as gastrointestinal carcinoma, in which operation is contemplated in the presence of severe malnutrition which cannot be corrected by a high protein diet. The preoperative preparation in such cases with parenteral protein will lower mortality, facilitate surgery and reduce complications. To be included in this group also are postoperative cases in which abdominal operations have been performed and in which nothing by mouth is permitted in order to achieve gastrointestinal rest so that healing may occur. In such cases, too, protein starvation will obviously occur unless nourishment is given parenterally. Many manifestations of protein starvation can thus be avoided and the clinical condition be so improved thereby that a full diet by mouth can be started much earlier than when the parenteral injections are limited to water, salts and glucose.

Patients suffering from advanced inanition must also be included in this group. Amino acid therapy recently has been shown capable of saving many lives from the late, or what might be called the hitherto irreversible, stage of starvation. In the present war thousands, perhaps millions, have already died because of inanition. Many more will die even if food is made available for them. It has been known for a long time that after a certain point in progressive starvation a fatal outcome cannot be avoided because the gastrointestinal tract becomes incapable of function. Fluid or food cannot be swallowed or, if given by tube, is vomited or provokes diarrhea. In the recent (1943) famine in India Krishnan and his co-workers[6c] showed for the first time that the intravenous injection of a solution containing hydrolyzed protein and glucose reduced considerably the mortality in these late cases. Injections of glucose alone, of saline solution, plasma or blood proved relatively ineffective. Only a few injections, averaging three, of the hydrolyzed protein solution were necessary. After this treatment patients were revived and able to start taking food and fluid by mouth. These investigators reported 5,000 injections with few untoward reactions, none of them serious. Their hydrolysate was a papain digest of pork.

B. Patients able to ingest protein but in whom the amount is inadequate or difficulty is encountered in digestion or absorption: In this group of cases amino acids may sometimes be given orally, but in many they will have to be given parenterally. This group includes a wide variety of diseases, particularly those in which severe malnutrition has developed because of the patient's inability to take sufficient food. After a certain period of malnutrition, the gastrointestinal tract becomes incapable of digesting a sufficient amount of protein food, especially if edema of the gastrointestinal tract is present, and vomiting or diarrhea may result. Sparing digestion

by giving amino acids orally will sometimes obviate the difficulty, as reported by Olmsted,[7] but in many cases the oral intake of food will have to be supplanted or supplemented for a time by intravenous administration in order to insure a sufficient intake. This is true of those with extreme malnutrition, as just described, but is not infrequently seen after severe injuries and extensive thermal burns. In other cases digestion or absorption is impaired because of severe gastroenteritis, ulcerative colitis or regional ileitis, so that food by mouth provokes severe diarrhea and thus digestion and absorption are prevented. In such a case also the substitution of amino acids for whole protein by mouth may, by sparing the necessity for digestion, result in adequate absorption, although in many cases it will be advisable to put the gastrointestinal tract completely at rest by giving nourishment parenterally. To be included in this group are certain types of intestinal fistulas in which profuse discharge of undigested contents escape.

C. Other indications including patients with allergy and intractable and especially bleeding peptic ulcer: In cases of extensive protein allergy the use of amino acids instead of whole protein will frequently avoid this difficulty and they have been used as such by a number of observers, especially in infancy, with very favorable results.[8] Olmsted [7] has used amino acids also during the diagnostic period in severe food allergy, thus avoiding the usual starvation which otherwise occurs. In peptic ulcer the use of amino acid mixtures orally has proved effective on purely clinical grounds with evidence of healing, as shown by x-ray examination in a series of peptic ulcers previously refractory to medical therapy as reported by Co Tui.[9] In a series of bleeding peptic ulcers a similar regimen of oral amino acids has been shown by Levy [10] to result in a much more rapid recovery than in cases in which the ordinary regimen of whole protein food has been employed. This may be due to the fact that the administration of amino acids not only permits protein nourishment without the need for digestion but has an additional advantage in that amino acids act as a buffer and thus tend to neutralize gastric acidity, as shown by Levy and Siler.[11]

THE ORAL USE OF AMINO ACIDS

The use of amino acids by mouth is therapeutically desirable in that it avoids the necessity of protein digestion. Thus it would seem that larger amounts of protein nourishment could be administered in this way and more rapid correction of protein deficiencies in extremely malnourished patients achieved. While clinical experience is not extensive, it has been my [12] observation that, in many of these patients in whom the ingestion of protein food provokes diarrhea or even vomiting, the substitution of amino acids permits absorption without difficulty. This would seem to be especially true of jejunal feeding; for example, Mulholland and his associates [13] have administered oral amino acids very soon after gastric resection through a jejunal tube passed across the stomach at the time of operation. They have succeeded in administering a 3,000 calory, 200 gram protein diet in this way with striking improvement in postoperative asthenia and rapidity of convalescence.

Amino acids dissolved in water, milk or juices may be taken by mouth. However, the taste of some of the commercial preparations available at present is unpleasant. Attempts have been made to flavor the solution but these have not been entirely successful, although the taste can be partially disguised in a number of ways. One method which has been employed by Co Tui is to stir 20 Gm. of the powdered protein hydrolysate in a small amount of water and ask the patient to follow it up with 20 Gm. of a sugar solution as a chaser. This is done ten to fifteen times a day and thus permits the ingestion of 200 to 300 Gm. of protein substance in the form of amino acids in twenty-four hours.

Tube Feeding.—The unpleasant taste of some amino acid preparations may be avoided by the use of tube feeding. Obviously a jejunostomy or a gastrostomy tube inserted at operation avoids the disadvantages of passing and retaining a nasal or an oral catheter. On the other hand, jejunal feeding by tube can also be achieved without an additional abdominal incision by inserting the tube across the lumen of the stomach into the lumen of the jejunum at the time of operation usually performed for gastric resection. This permits gastric rest and has been described in detail by Ravdin [14] and Mulholland.[13] Ordinarily, however, tube feeding requires the passage of a catheter into the stomach through the nose or mouth. Twenty Gm. each of a protein hydrolysate and simple carbohydrate in about 200 cc. of water may then be administered ten or fifteen times a day during day and night if desired, thus permitting the large intake of 200 to 300 Gm. of protein nourishment along with the same amount of carbohydrate.

While amino acids and glucose alone are the simplest formula for oral feeding, a more complete diet may easily be administered by adding fat according to the technic devised by Olmsted.[7] Olive oil is emulsified with the aid of gelatin, and the amino acids and carbohydrates are then added. Olmsted has been able to administer large amounts of food through a gastric tube in cases of severe malnutrition and start the patient on the road to nutritional recovery much more effectively and rapidly than is possible through persuasion or other methods using protein foods. Other suggestions for the addition of amino acids in tube feeding will be found in the paper of Lund and Levenson and others in this series.

It should be mentioned, of course, that vitamin mixtures must be added to the amino acids fed by mouth. Any of the preparations on the market may be used, particularly those that are available in liquid form. An adequate amount is simply added to the mixture given by tube.

PARENTERAL ADMINISTRATION OF AMINO ACIDS

The parenteral administration of protein food by means of amino acids represents as great an advance in therapy as the injection of glucose as a means of supplying calories or of water and electrolyte in maintaining water balance and in correcting dehydration, or as the injection of crystalline vitamins in combating vitamin deficiencies. Indeed, the addition of amino acids to the usual parenteral fluids makes possible the

administration of an almost complete diet without recourse to the usual digestive processes. Thus starvation can be avoided almost completely even though the patient is unable to take anything by mouth. Complete rest of the gastrointestinal tract, which heretofore inevitably resulted in protein starvation, can now be achieved with an almost full dietary intake. Thus both food and rest can be utilized; both factors are obviously very important in the healing of many types of lesions both surgical and medical. To limit the parenteral diet to water, electrolyte, glucose and vitamins is no longer justified; the addition of amino acids makes the mixture more nearly complete.

Methods of Parenteral Administration.—Preparations of hydrolyzed protein are available as sterile solutions ready for intravenous injection or in the form of a powder which with appropriate care and facilities can be made into a solution for intravenous use. The mixture which I recommend is one containing 5 per cent protein hydrolysate, 5 per cent glucose and 0.2 per cent sodium chloride. A liter of such a solution provides four of the necessary nutritional elements: water, salt, carbohydrate and protein. It should be emphasized, of course, that the biologic value of any amino acid mixture or preparation of hydrolyzed protein depends on its content of essential amino acids, and this in turn depends on the proteins selected for hydrolysis as well as the details of the procedure itself. It is therefore important for the physician to be sure that any solution he uses has been sufficiently tested in order to demonstrate that it contains a sufficient concentration of all the essential amino acids to maintain normal protein metabolism.

The rate of injection of hydrolyzed protein cannot be too great lest symptoms of nausea and vomiting be produced. This rate is somewhat slower than that usually given for glucose solutions alone; e. g., for 1 liter containing 5 per cent protein digest and 5 per cent glucose a two hour period is usually required in an average sized adult. Great individual variations are observed and it is often permissible to let the patient adjust the rate of flow himself. In many cases a liter will run in during one and one-half hours with no unpleasant subjective symptoms, in others such a rate will provoke nausea, a feeling of warmth and occasional slight abdominal pain or perhaps other unpleasant symptoms. A two hour period is really required for full utilization of the injected glucose and amino acids; a more rapid rate may permit loss of either in the urine, though the amount is not very great even with a one hour injection.

Injections are best given a liter at a time, one in the morning and one in the afternoon. If the injection supplements food by mouth it should be given in the evening or after the last meal so as not to interfere with the eating of food.

Deleterious Effects.—No intravenous injection can be given with impunity; the possible dangers have been sufficiently emphasized by many and great care must always be exercised regardless of the solution given. The physician must remember, however, that a solution of amino acids is an excellent culture medium and particular care must be taken to prevent contamination. In this sense, it is similar to whole blood and plasma except that bacterial growth is much more apt to occur in amino acid solutions. Pyrogenic reactions may be produced by such contamination. Even with utmost care and elimination of bacterial growth solutions of amino acids are potentially as capable of provoking reactions when given intravenously as plasma or whole blood transfusions, although at the Barnes Hospital they have been less frequent than those experienced with plasma or whole blood when given with the same type of tubing and with the same care. Careful scrutiny was made of all injections during the past four months. Of 865 liters injected intravenously during this time, there were seven reactions. None were serious, and a few were extremely mild.

Subcutaneous Injections.—Amino acids may be injected subcutaneously as well as intravenously except that, like glucose, the solution should be isotonic with the blood and neutral in reaction. Thus a mixture containing 5 per cent glucose and 5 per cent amino acids should be diluted with an equal quantity of distilled water to provide isotonicity in order to achieve a maximum degree of absorption and a minimum degree of local reaction. An isotonic solution obviously requires the use of a larger volume of fluid than is necessary with intravenous injection.

TABLE 3.—*A Program for Daily Parenteral Feeding (Including Amino Acids)* *

Initially larger doses and plasma or whole blood transfusions may be required to meet acute deficits.

		Actual Amount of Nutriments				
	Solutions Required	H_2O, Cc.	Salt, Gm.	Glucose, Gm.	Protein as Amino Acids, Gm.	Calories
A. No protein depletion	Protein hydrolysate 5%-glucose 5%, 1 liter; glucose 5%, 1 liter; isotonic solution of sodium chloride,† 1 liter	3,000	11	100	50	600
B. Moderate protein depletion	Protein hydrolysate 5%-glucose 5%, 2 liters; isotonic solution of sodium chloride,† 1 liter	3,000	13	100	100	800
C. Severe protein depletion	Protein hydrolysate 5%-glucose 5%, 3 liters	3,000	6	150	150	1,200

* Vitamins are given separately. In certain surgical patients vitamin C is especially indicated in doses of 1 Gm. per day.

† After severe operations it may be inadvisable to inject saline solution in view of the evidence indicating the existence of a postoperative intolerance to salt (Coller, F. A., and others: Postoperative Salt Intolerance, Ann. Surg. 119:533, 1944). In such cases 5 per cent glucose in water is substituted for the isotonic solution of sodium chloride.

Plasma versus Amino Acids.—Plasma transfusions are also a means by which protein can be introduced parenterally and must be discussed in contrast to the method already described with amino acids. Actually, both ways of introducing protein substance have distinct indications and often should be used in the same patient. Plasma offers an immediate and often life saving method of replacing plasma protein depleted by hemorrhage, burns or other acute diseases. It should be emphasized that for such rapid replacement plasma represents but half of the blood and that, when red cells are lost, whole blood rather than plasma should be given. However, when plasma proteins have been depleted because of malnutrition, the use of transfusions as the sole source of protein has been disappointing largely because of the fact that the injected protein fails to remain in the circulating blood but leaves very rapidly, apparently in an attempt to replace protein deficiencies throughout the body. As a sole source of protein, moreover, plasma transfusions are expensive and inconvenient. Thus, 60 Gm. of protein administered in this way requires the bleeding of 4 donors, and processing.

Large and repeated plasma transfusions, unlike the use of amino acid solutions, may lead to reactions. Actually but little is known of the metabolic behavior of plasma protein when injected into the blood stream. Knowledge of the fate of the injected plasma protein is important in view of the fact that this method of introducing protein food has no counterpart in any normal physiologic process. The intravenous injection of amino acids, on the other hand, represents a physiologic method in that it is a normal way in which protein food enters the blood stream from the gastrointestinal tract. Nevertheless, in nutritional hypoproteinemia one or more ordinary plasma or whole blood transfusions are excellent supplementary procedures. Moreover, when plasma or whole blood are the only fluids available for the parenteral administration of protein they should be used in larger amounts and will exert considerable clinical benefit.

A PLAN FOR PARENTERAL FEEDING

Before undertaking the administration of amino acids by injection, the physician should determine as far as possible the amounts required and add to this the other nutritional requirements. This is an important consideration because each substance requires the presence of the others in order to be most completely effective. Water balance is often disturbed in protein deficiency; carbohydrate is needed for utilization of fat and protein; vitamins play an important part in carbohydrate and probably in protein utilization. The use of all these substances in appropriate amounts is therefore essential in planning such a parenteral diet. In planning the dose of parenteral fluids in each case it is of considerable value to distinguish between acute deficits and amounts required for maintenance. It should be emphasized, however, that any parenteral method is inconvenient, expensive and not without danger and should not be used with complacency. It should be employed for specific indications, only as much given as needed, and replaced as soon as possible by the normal oral route.

Acute Deficiencies in Dehydrated Patients.—Several liters of fluid up to 5 may be required to correct dehydration. Under certain circumstances special fluids for the treatment of acidosis and alkalosis also are indicated. Plasma or whole blood transfusion will similarly be required to correct acute hypoproteinemia and anemia. This type of parenteral therapy is fairly well known and really does not fall within the province of the present discussion. It is mentioned because such injections must always precede a plan for meeting the daily needs.

Daily Requirements.—It is probable that for short periods a complete caloric intake may be sacrificed in view of the fact that in many instances much of the caloric needs may safely be supplied by tissue fat.[14a] This is permissible except in the case of malnutrition in which tissue stores of fat have been exhausted. In such instances the administration of fat intravenously has great practical advantages and will probably be available in the near future but at present cannot be used.

For surgical or other patients unable to take food by mouth, a simple plan may be drawn up in which all of the nutritional elements can be introduced intravenously in a volume of 3,000 cc. This amount of water is probably necessary in most cases for maintaining water balance and providing a urinary output of about 1,000 cc. or more per day. Of the 3 liters, 1 liter at least should contain 5 per cent protein digest and 5 per cent dextrose. Of the other 2 liters 1 will contain 5 per cent dextrose in water and the other isotonic solution of sodium chloride, which can be injected subcutaneously, thus relieving the patient of the long period required for the administration of 3 liters of fluid into the vein. This should suffice in the average case in which no severe protein, salt or water deficiency is present at the time of operation.

In more severely depleted patients 2 liters instead of 1 liter of 5 per cent protein hydrolysate and 5 per cent glucose should be given; the remaining liter will consist of either isotonic solution of sodium chloride or 5 per cent glucose in water, the former having the advantage of being injectable under the skin.[15] In the cases of most severe protein depletion, all of the 3 liters should consist of 5 per cent amino acid preparation and 5 per cent glucose. In table 3 is listed the total intake in the three types of programs just outlined.

14a. Elman, R.; Davey, H. W., and Kiyasu, R.: J. Lab. & Clin. Med. 30: 273, 1945.

15. While many surgeons give 5 per cent glucose by hypodermoclysis with satisfactory result, I do not do so because I feel that it is slowly absorbed and apt to be irritating as compared with isotonic solution of sodium chloride. As regards amino acids, the same can be said as for glucose provided the reaction of the solution is neutral; hypodermoclysis can be used by merely diluting the 5 per cent amino acid, 5 per cent glucose solution with an equal amount of distilled water. In children this has been employed in a more concentrated mixture (Hartmann, A. F., and others: J. Pediat. 24: 371, 1944).

Council on Industrial Health

SELECTED PUBLICATIONS IN INDUSTRIAL HEALTH

The office of the Council on Industrial Health is frequently asked to recommend publications relating to industrial medicine, surgery and hygiene. The list of textbooks and periodicals which follows was compiled from information furnished by the chairmen of committees on industrial health in the state medical societies, directors of industrial hygiene bureaus in state and federal agencies, and by two hundred full time industrial physicians throughout the country.

C. M. PETERSON, M.D., *Secretary.*

Books

GENERAL TREATMENT

Division of Industrial Hygiene, National Institute of Health, United States Public Health Service: Manual of Industrial Hygiene. $3. Pp. 508. Philadelphia, W. B. Saunders Company, 1943.

International Labour Office: Occupation and Health, Volume I, pp. 999. Geneva, 1930. Volume II, pp. 1,310. Geneva, 1934. $24 set. Supplements, Geneva, 1938, 1939, 1940, 1944, 25 cents each.

Wampler, Fred J.: The Principles and Practice of Industrial Medicine. $6. Pp. 579. Baltimore, Williams & Wilkins Company, 1943.

Sappington, C. O.: Essentials of Industrial Health. $6.50. Pp. 626, with 63 illustrations. Philadelphia, J. B. Lippincott Company, 1943.

Lanza, A. J., and Goldberg, Jacob A.: Industrial Hygiene. $8.50. Pp. 743. New York, Oxford University Press, 1939.

Kober, George M., and Hayhurst, Emery R.: Industrial Health. $15. Pp. 1,184, with illustrations. Philadelphia, P. Blakiston's Son & Co., 1924.

Rosenau, Milton J.: Preventive Medicine and Hygiene. Ed. 6. $10. Pp. 1,481. New York, D. Appleton-Century Company, 1935.

Clark, W. Irving, and Drinker, Philip: Industrial Medicine. Ed. 2. $3. Pp. 262. New York, National Medical Book Company, Inc., 1935.

INDUSTRIAL MEDICINE AND SURGERY

Schwartz, Louis, and Tulipan, Louis: A Text-Book of Occupational Diseases of the Skin. $10. Pp. 799, illustrated with 116 photographs. Philadelphia, Lea & Febiger, 1939.

Johnstone, Rutherford T.: Occupational Diseases; Diagnosis, Medicolegal Aspects and Treatment. $7.50. Pp. 558, illustrated. Philadelphia, W. B. Saunders Company, 1941.

Sappington, C. O.: Medicolegal Phases of Occupational Diseases. An Outline of Theory and Practice. $2.75. Pp. 405. Chicago, Industrial Health Book Company, 1939.

Kessler, Henry H.: Accidental Injuries—The Medicolegal Aspects of Workmen's Compensation and Public Liability. Ed. 2, enlarged and thoroughly revised. $10. Pp. 803, illustrated with 202 engravings. Philadelphia, Lea & Febiger, 1941.

White, R. Prosser: The Dermatergoses or Occupational Affections of the Skin, Giving Descriptions of the Trade Processes, the Responsible

Agents and Their Actions. Ed 4 Pp 716, with 66 plates, including 72 figures London, H K Lewis & Co Ltd, 1934

Lanza, A J Silicosis and Asbestosis $4 25 Pp 439 New York, Oxford University Press, 1938

Resnick, Louis Eye Hazards in Industry—Extent, Cause and Means of Prevention $3 50 Pp 321 New York, Columbia University Press, 1941

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application

AUSTIN SMITH, M D, *Secretary*

SCARLET FEVER STREPTOCOCCUS TOXIN FOR THE DICK TEST (See New and Nonofficial Remedies, 1944, p 577).

The following dosage form has been accepted

WYETH, INCORPORATED, PHILADELPHIA

Scarlet Fever Streptococcus Toxin for the Dick Test: 2 cc and 10 cc vials containing sufficient diluted toxin for withdrawal to perform five and fifty tests, respectively. Preserved with 0 4 per cent phenol

PYRIDOXINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1944, p 618)

The following additional dosage form has been accepted.

LAKESIDE LABORATORIES, MILWAUKEE

Tablets Pyridoxine Hydrochloride: 20 mg

DIETHYLSTILBESTROL (See New and Nonofficial Remedies, 1944, p 417).

The following dosage form has been accepted

THE UPJOHN COMPANY, KALAMAZOO, MICH.

Perles Diethylstilbestrol: 5 mg

SULFAMERAZINE (See Supplement to New and Nonofficial Remedies, 1944, p 10)

The following dosage form has been accepted

THE UPJOHN COMPANY, KALAMAZOO, MICH.

Tablets Sulfamerazine: 0 5 Gm

NICOTINAMIDE (See New and Nonofficial Remedies, 1944, p 617)

The following dosage form has been accepted

PITMAN-MOORE CO., INDIANAPOLIS

Solution Nicotinamide 100 mg. per 2 cc.: 2 cc. ampuls.

SYNTHETIC OLEOVITAMIN D (See New and Nonofficial Remedies, 1944, p 623)

The following dosage form has been accepted

AMERICAN PHARMACEUTICAL CO., INC., NEW YORK

Viosterol in Oil: 10 cc and 50 cc bottles. Viosterol in vegetable oil

RIBOFLAVIN (See New and Nonofficial Remedies, 1944, p 613)

The following additional dosage form has been accepted

MEAD JOHNSON & CO., EVANSVILLE, IND.

Tablets Riboflavin: 5 mg

REHABILITATION AND REEMPLOYMENT

As the rehabilitation program unfolds, medicine must assume responsibility for competent treatment and reconditioning, followed by placement in occupations based on a medical evaluation of residual ability rather than disability. From the latter concept selective placement has emerged. Selective placement demands the matching of the physical, mental and emotional capacity of an individual, his intelligence, talents, skills, experiences, desires and motivations with the technologic and physical demands of a given job.

Placement has long been practiced by private industry. Reported observations of success or failure have been relatively few. The Council on Industrial Health will shortly sponsor jointly with the Veterans Employment Service and the Occupational Analysis Division of the War Manpower Commission a controlled experiment in selective placement. The essential elements will be an adequate psychosomatic evaluation of a worker by a qualified examining physician, a job description by an occupational analyst, suitable attention to environmental hygiene and sanitation, and the application of the matching technic by medical and employment officers. Ultimately the experiment will extend to various kinds and sizes of industrial plants and to normal as well as subnormal workers. Any procedure which brings the right man and the right job together appeals to industry as a desirable objective from the varying points of view of human relations, health, safety and production.

Selective placement expresses capacity for work in terms of ability rather than of disability. The medical profession has struggled endlessly with efforts to define and determine disability. Methods have not yet been devised which do not yield wide variations in interpretation by different individuals. Percentage determination of disability has led to flagrant abuses in claim adjudication both in workmen's compensation affairs and in common law. The more positive approach which evaluates what a man has left rather than what he has lost should appeal to physicians as more amenable to logical and scientific appraisal.

Of the two major programs in rehabilitation, veteran reemployment still overshadows the activities of the state rehabilitation agencies now developing under the egis of the federal Office of Vocational Rehabilitation. Many industries, recognizing their obligations for veteran reemployment under the Selective Service and Training Act of 1940, have developed comprehensive procedures which include medical examination and placement. A feeling is growing, however, that reemployment of veterans is a community responsibility requiring participation of all social agencies as well as employers. Just what will be expected of the medical profession under such an arrangement is not altogether clear. Employers will however be interested in preplacement physical appraisal of disabled veterans. The Committee on Rehabilitation and Employment of the Council on Industrial Health is developing a series of recommendations about veteran reemployment for the guidance of physicians and medical organizations. The procedure which is being developed will avoid duplication of physical examinations either through central registration in a community reemployment center or by means of a card issued to the worker bearing essential data, which can be presented at the time of any interview.

INDUSTRIAL HEALTH—POSTWAR

Currently the demand for health services in industry is greater than the medical and allied professions are prepared to meet. Will this interest maintain itself after the stimulation of war production is over? Reconversion has already curtailed medical activity in a few war plants; on the whole, however, optimism is warranted as to the postwar course of industrial medicine. Certainly governmental agencies, committed to capacity peacetime employment and production, are not likely to moderate present activity in industrial hygiene or workmen's compensation. At the moment proposals are under consideration to expand industrial hygiene services in both federal and state health agencies to a considerable degree, through earmarked allotments in the budget of the U. S. Public Health Service. Furthermore, legislation now under consideration would make available to all federal employees occupational health services similar to those furnished by private industry. Extension into the states and municipalities will provide service to millions of government wage earners. Labor is more and more alive to its own responsibilities for health conservation and education. Safe and healthful working conditions are unquestionably here to stay as factors in collective bargaining. Management, through its national organizations and trade associations, has recognized the objectives of industrial health and is actively advocating their widespread

adoption. Medicine has accepted greater individual and collective responsibility for industrial health service than ever before.

Observers of industrial medical activity note its uneven distribution. Medicine and industry have not developed a formula which presents the benefits of industrial health service convincingly enough to attract full support from the great majority of small plant owners. Past demonstrations have shown that such services can be furnished within the means of almost any employer by using various combinations of part time service of physicians and nurses. One especially promising experiment is taking place in the Fort Greene District of Brooklyn, where the county medical society and the local health agency have joined forces with employers, labor and social agencies to promote a plan of health education sponsored by plant labor-management health committees. On this foundation the larger superstructure of a plant medical service can be built. In nearby Astoria, nursing and industrial hygiene services are supplied to small industry provided the plant employs a physician and complies with other requirements which include proper medical supervision and adequate record keeping. In time the employer will no doubt assume full support of the project.

Special medical services of various kinds will probably be introduced rapidly in the postwar period. There are few independent consultants in industrial hygiene, sanitation or ventilation. Clinical pathologists who have some acquaintance with toxicology could well expand their professional horizons to provide consultation service to industry. Psychiatrists working with clinical psychologists may contribute greatly to those aspects of human relations and behavior which have proved troublesome in our industrial civilization. Serious consideration, in fact, has already been given to the development of industrial medical clinics. They will provide conventional industrial procedure plus a diagnostic service which will supplement and make more effective the efforts of the worker's personal physician in the field of nonindustrial disorders.

Much interest is apparent by management and by labor regarding the extension of industrial medical services to include ordinary illness. Many variations in approach have been developed by such diverse industries as mining, shoe manufacturing, refining, ship construction and transportation. The Council on Industrial Health has taken the position that the principles on which medical care should be based have been defined by the House of Delegates of the American Medical Association. If medical care plans are in prospect, industry should be in agreement with the appropriate medical societies as to conformity of such plans with these established principles. Since these plans are essentially medical, the Council feels that policies should be directed and controlled by medical departments in industry.

INDUSTRIAL MEDICAL EDUCATION

The Committee on Postwar Medical Services has been inquiring into the postwar intentions of medical officers in the Army and Navy.[1] Out of over 20,000 questionnaires returned 4,215 officers indicated a desire for industrial medical practice, 863 of them full time. About one third of this group wanted special preparation. The questionnaire did not determine specifically the desire of these men for long or short courses; the impression is clear that university courses are preferred over training in industry itself.

According to a recent survey by the Council on Industrial Health, nine universities are prepared to supply advanced training in industrial health in schools either of medicine or of public health. Plans are maturing in a number of additional schools pending departmental organization, support or faculty assignments. These educational resources seem to be sufficient or susceptible of sufficient expansion to meet any immediate demand.

The Council on Industrial Health and the Council on Medical Education are jointly examining the whole industrial medical education structure in the expectation that suitable recommendations can be made for orderly development.[2] Full consideration will be given the details of undergraduate orientation, refresher and continuation courses, internships and residencies as well as fellowships or other long courses of a caliber similar to those demanded in other fields of graduate medical preparation for specialization.

SENATOR WAGNER'S COMMENTS

In the Organization Section in this issue of THE JOURNAL appears a second communication from Senator Wagner, commenting on the editorial and the condensation of his bill which appeared in THE JOURNAL, June 2. Because Senator Wagner occupies a position of importance in the legislative machinery of the United States government and because he has been persistent in his endeavor to force upon the American people a federal system of compulsory sickness insurance, THE JOURNAL prints in toto his comments on its editorial. Interpolated in his longer communication are a number of simple replies to the points that he raises. The Wagner-Murray-Dingell bill—1945 version—is 185 pages long. It is simply impossible, with the space available, to make the detailed line-by-line analysis of this proposal that will be necessary should it ever come to public hearings.

Almost coincidental with the introduction of this measure came another bill—Senate bill 380—developed by Senators Wagner, Murray, O'Mahoney and Thomas.

1. Lueth, H. C.: The Medical Officer and Future Industrial Medical Practice, J. A. M. A. **128**: 93 (May 12) 1945.
2. Bristol, L. D., and Peterson, C. M.: Industrial Health, J. A. M. A. **125**: 1106 (Aug. 19) 1944.

In his consideration of that measure Mr. Raymond Moley, editor of *Newsweek* Magazine, says "It is an old gag of Senator Wagner's to preface a bill with a bunch of rhetorical tripe called a declaration of policy. He knows, as a lawyer, that this preamble has no standing in court. But, as a politician, he knows that such stylistic flypaper snares votes and praise." The statement refers equally well to the long preamble developed by Senator Wagner for introduction to the Wagner-Murray-Dingell bill—1945 version—and certainly applies to the letter published in this issue of THE JOURNAL. Mr. Moley concludes that "'full employment,' literally enforced, would mean the end of freedom for all classes of Americans."

It is the simple contention of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION that the Wagner-Murray-Dingell bill—1945 version—would also mean the end of freedom for all classes of Americans.

Current Comment

STRUGGLE OVER DOGS

Recently newspapers in Chicago have described another clash between the antivivisectionists and a Chicago medical school. Despite repeated hearings in which they always fail to establish their charges, the antivivisectionists continue to oppose the Chicago ordinance which requires the pound to deliver unclaimed dogs to the medical schools. Mrs. Charles M. Petkus, vice president of the Illinois Citizens Animal Welfare League, has been insisting that Northwestern University keeps its dogs under insanitary and filthy conditions. The Chicago *Herald American* has given much publicity to Mrs. Petkus' activities; other newspapers have treated the whole situation either with brevity or with mild derision. Investigations of Mrs. Petkus' charges have not sustained her claims. On June 12 Mrs. Petkus took a dog out of a cage during an inspection tour through Northwestern's animal rooms and attempted to carry the animal away. According to their story, Mrs. Petkus and two other women with her were resisted. One of Mrs. Petkus' companions was Mrs. Irene Castle McLaughlin. A lieutenant colonel of the Army Medical Corps, just returned from overseas service, makes the following comment in a letter published in the Chicago *Daily News* of June 18:

> This morning I returned to Chicago after more than forty months overseas, where I commanded a portable surgical hospital and a field hospital.
>
> Upon my arrival I bought my first *Daily News* in nearly four years. My attention was drawn to the article about Mrs. Irene Castle McLaughlin and her antivivisectionist friends interfering with Northwestern University's Dr. Ivy, an internationally famous physiologist and undoubtedly the benefactor, through his work, of many millions of people.
>
> I studied at Loyola University and was introduced to surgery in the vivisection laboratory. The surgery I practiced in Chicago and later on the front lines and the surgery practiced by the vast majority of both civilian and military surgeons was begun in the vivisection laboratory.
>
> There can be no dispute that surgery in this war is saving lives and limbs of thousands of servicemen who would die had their surgeons been less well trained—and had they not at least begun their training by vivisection.
>
> I believe the people of Chicago are entitled to know what Mrs. McLaughlin has done for the war effort that she thinks entitles her to interfere with the training of our surgeons.

PHYSICIANS AS CULTURAL ATTACHÉS

The suggestion has been made recently that the post of cultural attaché in the United States embassies, if it is to be maintained, should be extended to all countries, and that those who fill these posts be men or women of distinction in fields of higher intellectual or artistic endeavor. In discussing this matter Vaillant [1] points out the undeniable fact that a man who is not a physician is not able to estimate the abilities of members of the medical profession. Few physicians would care to make a career of being a "cultural attaché" and, as Vaillant says, the name itself would be a contradiction as a permanent job. A physician serving in this capacity, however, could perform a national service and would receive an instructive interlude of his usual professional activity. A physician who was appointed for one or two years as a cultural attaché doubtless would be expected to evaluate medical problems of the country in which he was stationed and the qualifications of physicians there. As an eminent physician himself, he should lend distinction to the embassy staff in the eyes of a large and influential professional group. Indeed, a physician attached to a United States embassy would often be in a position to render valuable service not only to his government but also to the country to which he was accredited. For the physician himself and for medicine in the United States such a practice would have much to recommend it. It would be an enriching experience for a man already established in medicine to spend one or two years doing responsible work in some other country. The return of physicians with their experience of medicine in other lands would help to counteract what Osler called chauvinism in medicine. If the State Department continues and extends the policy of the "cultural attaché" the appointment of some qualified physicians would be desirable.

HEPATITIS TRANSMITTED BY SYRINGE

In a period of two years, January 1943 to January 1945, 63 patients with diabetes who attended a clinic at the Royal Hospital in Sheffield, England, were diagnosed as suffering from hepatitis. Four patients died and 6 patients were left with evidence of residual liver damage. According to Droller,[1] the epidemiologic picture was complex. The cases of hepatitis arose both from contact between patients and from syringe transmission. There was, however, conclusive evidence that some of the cases resulted from contaminated syringes and this outbreak therefore demonstrates the possibility of the development of hepatitis by such means.

MEDICINE AND THE WAR

ARMY

MERITORIOUS SERVICE AWARD

The AAF Regional Hospital, Truax Field, Wisconsin, was recently awarded the Meritorious Service Unit Plaque for "superior performance of duty and outstanding devotion to its assigned mission for the period Jan. 1, 1944 to Dec. 31, 1944."

COLONEL FLORENCE A. BLANCHFIELD AWARDED MEDAL

Col. Florence A. Blanchfield, superintendent of the Army Nurse Corps, was recently awarded the Distinguished Service Medal "for exceptionally meritorious and distinguished service as superintendent of the Army Nurse Corps from June 1943 to June 1945." The medal was presented to Colonel Blanchfield by General Brehon Somervell, commanding general, Army Service Forces. "The War Department has cause to be proud of the work done by army nurses," General Somervell said, "but I can pay no greater tribute to yourself and the women of the Army Nurse Corps than to tell you that, to a man, the American soldier appreciates the work and spirit of devotion with which army nurses throughout the world have carried on their duties." Colonel Blanchfield, whose home is at Shepherdstown, W. Va., entered the Army Nurse Corps in July 1917, serving overseas in the first world war with Base Hospital No. 27. She has been assigned to the Surgeon General's Office since 1935. As superintendent, she is responsible for one of the most important jobs of the war, that of establishing and maintaining efficient nursing care for the thousands of American sick and wounded soldiers all over the world. Colonel Blanchfield is the first army nurse to receive the Distinguished Service Medal in this war, although twenty-three were so honored in the first world war. The first American woman to receive the Distinguished Service Medal was Army Nurse Julia C. Stimson, May 26, 1919.

Assignment of Medical Officers to Veterans Administration

June 20, 1945

Dr. Morris Fishbein,
Editor, The Journal,
Chicago.

Relative your telegram 14 June, in future Medical Corps officers will not be assigned to Veterans Administration unless they were previously employed by that agency or they specifically request such assignment.

KIRK
Office of the Surgeon General
Washington, D. C.

CONVALESCING VETERANS GET WAR DOGS

Veteran war dogs, those no longer suitable for combat because of over age and those not adaptable to scout duty, are being assigned to army convalescent hospitals as pet mascots for recuperating patients. If a hospitalized veteran soldier becomes attached to an individual dog, he may assume full ownership and take the dog home with him when he recovers and is released from service. Dogs given to the hospitals are those whose donors do not wish them returned, cannot be located or are willing to relinquish their claim to the dogs in favor of the convalescing soldier. The dogs have undergone retraining by the Quartermaster Corps at its War Dog Training Center, Fort Robinson, Neb., to remove all undesirable or aggressive traits acquired by reason of former training or combat duty. They have been given obedience training to reemphasize response to fundamental commands such as come, sit and stay.

ARMY AWARDS AND COMMENDATIONS

Captain Rex D. Hammond

Capt. Rex D. Hammond, formerly of Chicago, was recently awarded the Bronze Star for meritorious achievement. He had been with the 76th Medical Battalion, United States Third Army, since the invasion of Normandy and more recently became medical administrator of the Buchenwald Prison Camp. Dr. Hammond graduated from the University of Illinois College of Medicine, Chicago, in 1941 and entered the service Sept. 22, 1942.

Captain William E. Grove

Capt. William E. Grove, formerly of Newton, Kan., was recently awarded the Bronze Star "for meritorious service in connection with military operations against the enemy from Oct. 20, 1944 to Feb. 10, 1945 during the Leyte Island operations. During the entire campaign of the Leyte invasion Captain Grove performed his surgical duties in a very exemplary and outstanding manner. In spite of enemy bombings and lack of proper facilities on many occasions Captain Grove carried on his work. His devotion to the wounded was a great comfort to all who came under his care. In addition, from the period Dec. 23, 1944 to Feb. 10, 1945 Captain Grove was commanding officer of the organization and carried on his extra administrative duties with great ability. To compensate for the absence of one medical officer Captain Grove gave unstintingly of himself and often worked as long as five to six days with little or no rest. His professional and administrative capabilities, in spite of adverse conditions, served as an inspiration for and gained the admiration of the officers and enlisted men under his command." Dr. Grove graduated from Northwestern University Medical School, Chicago, in 1940 and entered the service Sept. 13, 1941.

Captain Rudolph Berke

Capt. Rudolph Berke, formerly of New York, was recently awarded the Bronze Star and shortly after was awarded the Oak Leaf Cluster. Dr. Berke graduated from the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, in 1930 and entered the service Sept. 16, 1942.

Captain Louie Goldberg

The Air Medal and one Oak Leaf Cluster was recently awarded to Capt. Louie Goldberg, formerly of Des Moines, Iowa, for service in air rescue of downed fliers. Dr. Goldberg graduated from the State University of Iowa College of Medicine, Iowa City, in 1936 and entered the service July 24, 1942.

Captain George L. Maison

The Legion of Merit was recently awarded to Capt. George L. Maison, formerly of Detroit. The citation accompanying the award read "for service from July 1942 to July 1944 as chief of the Acceleration Unit, Physiological Branch, Aero-Medical

Laboratory. He designed and developed the anti-G suit now used by A. A. F. fighter pilots to prevent blackout and to increase combat efficiency. This suit has had a beneficial effect in raising the score of enemy planes shot down by A. A. F. pilots. He demonstrated courage and forceful effort in developing this suit and demonstrating and instructing its use to the Eighth and Ninth Air Forces personnel." Dr. Maison graduated from Northwestern University Medical School, Chicago, in 1935 and entered the service April 16, 1942.

Major Ralph H. Riegelman

Major Ralph H. Riegelman, formerly of Des Moines, Iowa, was recently awarded the Bronze Star for "meritorious achievement as a group surgeon of a heavy bomb group and station surgeon of a station hospital in the North African and European theaters of operation from September 1942 to the present day. With no precedent to guide him and only limited personnel to work with, Major Riegelman established a most efficient station hospital to satisfy the many needs of an extensive combat operations program. By his diligence and devotion to duty he has successfully cared for the health of the group while operating from North Africa under adverse conditions. His skill, judgment, initiative, foresight and devotion to duty are most praiseworthy and reflect great credit on himself and on the armed forces of the United States." Dr. Riegelman graduated from the State University of Iowa College of Medicine, Iowa City, in 1936 and entered the service Dec. 12, 1940.

Captain Peter P. Baselice

The Bronze Star was recently awarded to Capt. Peter P. Baselice, formerly of New York, "for meritorious achievements in connection with military operations against the enemy at Sansapor, Dutch New Guinea and at ——, Philippine Islands, from Sept. 3, 1944 to March 20, 1945." Dr. Baselice graduated from the Royal University of Rome Faculty of Medicine and Surgery in 1935 and entered the service Aug. 18, 1942.

Major Ralph W. Wise

The French Croix-de-Guerre was recently awarded to Major Ralph W. Wise, formerly of Dallas Center, Iowa. The citation accompanying the award read, in part, "For exceptional services of war, rendered during the course of operations involving the liberation of France." Dr. Wise graduated from the State University of Iowa College of Medicine, Iowa City, in 1939 and entered the service Aug. 15, 1941.

Major Wayne C. Bartlett

Major Wayne C. Bartlett, formerly of Spearville, Kan., was recently awarded the Bronze Star for meritorious service. He has been overseas since August 1942, serving in an evacuation hospital as head of a surgical team. Dr. Bartlett graduated from Rush Medical College, Chicago, in 1931 and entered the service in May 1942.

Captain John H. Amesse

Capt. John H. Amesse, formerly of Denver, was recently awarded the Silver Star for gallantry in action during the Philippine Island campaign. In presenting this decoration, Brig. Gen. Hugh Hoffman of the 1st Cavalry Division stated that in each case this award is made by specific direction of the President. Dr. Amesse graduated from the University of Colorado School of Medicine, Denver, in 1941 and entered the service in July 1942.

MISCELLANEOUS

EIGHT AWARDED AMERICA TYPHUS COMMISSION MEDAL

Six army medical corps officers, one medical corps officer in the U. S. Naval Reserve and one officer in the sanitary corps were recently awarded the America Typhus Commission Medal. The recipients of the awards and the citations accompanying them include:

Col. Eugene W. Billick, formerly of Monongahela, Pa., who as chief surgeon, headquarters of the U. S. Army Forces in the Middle East, "rendered exceptionally meritorious service to the United States of America Typhus Commission by giving unstinted support to typhus research and control in the Middle East and the Balkans. His unfailing understanding of disease control and his ability to establish favorable liaison for the Typhus Commission with foreign governments and the armies of both the United States and Great Britain helped immeasurably in suppressing this fever throughout his sphere of influence. He also made available to the Typhus Commission in the winter of 1943-1944 personnel needed to combat an epidemic in Naples, Italy. His administrative actions and expert advice assisted materially in developing effective measures to prevent typhus in this theater of operations." Dr. Billick graduated from the University of Pittsburgh School of Medicine in 1925 and entered the service July 1, 1942.

Col. William L. Wilson, formerly of Washington, D. C., "performed exceptionally meritorious service in connection with the work of the United States of America Typhus Commission from September 1942 to May 1945 by giving valuable assistance and advice on numerous problems of policy, organization and operation. His wise counsel and excellent staff work greatly strengthened the commission. As deputy director of Public Health Section G-5, Supreme Headquarters, Allied Expeditionary Force, he influenced development of extensive plans for typhus control in northwestern Europe, particularly among refugees and displaced persons. He assisted materially in reducing the incidence of this disease." Dr. Wilson graduated from Baylor University College of Medicine, Dallas, Texas, in 1926 and entered the service Aug. 3, 1927.

Lieut. Col. Edward S. Murray, formerly of Cedar Rapids, Iowa, in Turkey in 1943-1944, in Egypt in 1944 and in Yugoslavia in 1945 "performed exceptionally meritorious service in connection with the work of the United States of America Typhus Commission. He had a prominent part in organizing and applying typhus control programs beneficial to those countries, and by scientific investigations he contributed to medical knowledge of typhus fever. In difficult and dangerous situations he steadfastly adhered to the plans of the commission and carried out projects on a national scale with energy, intelligence, tact and high professional competence. His performance of duties was characterized by breadth of understanding and capacity to deal successfully with large problems." Dr. Murray graduated from the State University of Iowa College of Medicine, Iowa City, in 1938 and entered the service Aug. 20, 1941.

Major William A. Davis, formerly of New York, both as a civilian and as an officer "performed exceptionally meritorious service in connection with the work of the United States of America Typhus Commission. In the winter of 1943-1944, while a staff member of the Rockefeller Foundation Health Commission, he gave valuable assistance in suppressing the typhus epidemic in Naples, Italy. After being commissioned he served as liaison officer representing the Typhus Commission with the 21st Army Group (British) from November 1944 to May 1945. In this position he assisted in formulating policy and organizing programs and participated in typhus control operations under campaign conditions in Belgium, the Netherlands, the Rhineland and at prison camps in Germany. His intelligent, energetic and professionally competent services were of great value to the Allied Expeditionary Forces in the enforcement of typhus control measures which reduced the incidence of this disease among refugees and displaced persons." Dr. Davis graduated from Harvard Medical School, Boston, in 1939.

Major Robert S. Ecke, formerly of Brooklyn, "performed exceptionally meritorious service in connection with the work of the United States of America Typhus Commission in several foreign countries. After successfully evaluating vaccination against typhus in Egypt in 1943 he helped control this disease among refugees in southern Italy during the 1943-1944 epidemic in Naples. Later in 1944 he carried out a valuable typhus survey and control program in the Aden Protectorate. In

June 1944 he made a survey of relapsing fever in the Anglo-Egyptian Sudan and in September 1944 a typhus survey in Ethiopia, each of which formed the basis for important decisions. During the spring of 1945 he pioneered typhus control in Yugoslavia. By his investigations he contributed new knowledge of typhus fever. Through constant and devoted service in situations requiring initiative and judgment he materially assisted in reducing the incidence of this disease." Dr. Ecke graduated from Johns Hopkins University School of Medicine, Baltimore, in 1935.

Major Chris J. D. Zarafonetis, formerly of Grand Rapids, Mich., "conducted investigations in the laboratory of the America Typhus Commission at Cairo, Egypt, during 1943-1944 which have increased the knowledge of immunity following vaccination against typhus. His researches contributed to development of improved methods of treating epidemic and scrub typhus. In July 1944 he made a survey of plague and typhus at Dakar and assisted in reducing the risk of infection of American troops. He has participated in pioneering work of control in Yugoslavia. From December 1944 to February 1945 he alone represented the commission in Greece, occupying a position of great responsibility in a military mission. Under the hardships of a civil war and at risks to his personal safety he carried out surveys and, in cooperation with local authority, formulated plans and procedures for typhus control. His service in Greece was an outstanding achievement." Dr. Zarafonetis graduated from the University of Michigan Medical School, Ann Arbor, in 1941 and entered the service July 1, 1942.

Lieut. Stafford M. Wheeler, M. C., U. S. Naval Reserve (posthumous), formerly of Boston, in Egypt during December 1944 and January 1945 and later in Yugoslavia "displayed special fitness for the work of the United States of America Typhus Commission. With other officers he was sent by the commission to Yugoslavia in February 1945 to assist in organizing and operating a typhus control program for that country. In difficult situations, under campaign conditions, he performed his duties with a high degree of intelligence, initiative and efficiency until killed at his work by the explosion of a land mine. He contributed materially to the advancement of the commission's typhus control program." Dr. Wheeler graduated from Harvard Medical School, Boston, in 1937.

Lieut. Col. Emory C. Cushing, Sanitary Corps, formerly of Arlington, Va., from 1942 "demonstrated unusual ability in developing and applying modern methods of typhus control. Drawing on his wide knowledge and experience, he gave expert advice on programs dealing with typhus control both for military personnel and among displaced persons and refugees. During 1944 and 1945 in the French and German campaigns he vigorously carried out disease control plans which he had helped formulate at an earlier date. His application of typhus control measures contributed greatly to a general reduction of the risks of infection in the western European combat zone."

CONTAGIOUS DISEASES AMONG DUTCH CHILDREN

A special release from the Netherlands Information Bureau states that infectious diseases due to malnutrition are continuing to take their toll among the children of the Netherlands. Thousands of youngsters are suffering from tuberculosis, dysentery and diphtheria, and the already overcrowded hospitals are unable to cope with the unprecedented demands on their services. Owing to the difficulty of obtaining nourishing foods in the western part of the Netherlands, tuberculosis is prevalent. Diphtheria and various skin diseases, including scabies, are particularly prevalent among babies and children under 4. Medical officials are doing all they can to fight disease, but they are hampered by a severe shortage of medicines, ointments, bandages and instruments. Even baby bottles, disinfectants and ingredients for such simple remedies as cough syrup are unavailable. Another handicap is the lack of sanatoriums for the hospitalization of tuberculosis victims. Doctors fear that home nursing of tuberculous patients may spread the disease to the rest of the population. In order to check any increase of various disease, repatriates from the concentration camps in Germany must undergo a strict physical examination, including a thorough delousing process, to prevent any possible typhoid epidemic. Furthermore, all of them are under obligation to take an x-ray examination for tuberculosis one week after their return to civilian life.

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

(Continuation of list in THE JOURNAL June 9, page 447)

ILLINOIS

Belmont Community Hospital, Chicago. Capacity, 125; admissions, 4,180. Mrs. Gertrude F. Scofield, Superintendent (interns, July and October 1945, January 1946).

KANSAS

Wichita Hospital, Wichita. Capacity, 157; admissions, 3,888. Sister M. Agnes, Administrator (interns, July and October).

MICHIGAN

Kalamazoo State Hospital, Kalamazoo. Capacity, 3,380; admissions, 542. Dr. R. A. Morter, Medical Superintendent (2 residents—psychiatry).

NEBRASKA

Creighton Memorial St. Joseph's Hospital, Omaha. Capacity, 501; admissions, 11,812. Dr. C. M. Wilhelmj, Dean, Creighton University School of Medicine (resident—pathology).

NEW JERSEY

Orange Memorial Hospital, Orange. Capacity, 439; admissions, 8,103. Mr. F. Stanley Howe, Director (intern).

PENNSYLVANIA

Uniontown Hospital, Uniontown. Capacity, 230; admissions, 5,563. Mr. John Farrell, Superintendent (interns).

UTAH

Thomas D. Dee Memorial Hospital, Ogden. Capacity, 400; admissions, 8,405. Mr. Lawrence H. Evans, Superintendent (interns).

CHILEAN ORDER OF MERIT

Col. Harold B. Gotaas, director of the Division of Health and Sanitation, Institute of Inter-American Affairs, was recently decorated by the Chilean government with the Order of Merit. Before joining the army in 1942 Colonel Gotaas was professor of sanitary engineering of the School of Public Health, University of North Carolina.

VETERANS ADMINISTRATION HOSPITAL IN PITTSBURGH

The Veterans Administration announced recently that President Truman has authorized construction at Pittsburgh of a 1,200 bed general medical and surgical hospital on a 13 acre site adjacent to the University of Pittsburgh. When the hospital is completed, the Aspinwall Hospital outside Pittsburgh will be converted into a tuberculosis hospital.

MEDICAL AND SURGICAL RELIEF COMMITTEE OF AMERICA

Following an appeal from the Maritime Hospital at Toulon, France, the Medical and Surgical Relief Committee of America (420 Lexington Avenue, New York 17) recently sent a supply of radium. In addition, the hospital received more than $5,000 worth of material from the committee, including an ambulance, penicillin and assorted medical and surgical supplies.

OCCUPATIONAL THERAPY EXPANSION

Between May 16 and 31 twenty-nine emergency course apprentices from Mills College, Calif., were assigned to hospitals for clinical training in occupational therapy. Seventy students were assigned to the War Emergency Course starting June 1 at Milwaukee Downer College, Milwaukee, and seventy-five enlisted women were assigned to occupational therapy assistants courses at Halloran General Hospital.

ORGANIZATION SECTION

THE WAGNER-MURRAY-DINGELL BILL

Senator Wagner Comments on The Journal Editorial Concerning the Wagner-Murray-Dingell Bill—1945 Version

(Following is a letter sent by Senator Wagner of New York to the editor of The Journal together with interpolated comment:)

To the Editor:—THE JOURNAL on June 2 published an editorial on the Wagner-Murray-Dingell bill. I should like to comment on this editorial.

In the last paragraph of your editorial it is stated that I have "not consulted with the American Medical Association." The fact is that I *did* consult the American Medical Association. On Dec. 7, 1944, I addressed a letter to Dr. Olin West, Secretary and General Manager of the American Medical Association, listing a series of suggestions for the revision of the 1943 bill and inviting the Association to comment on these proposals. In Dr. West's reply to me of December 15 he said that he was not in a position to enter into a discussion of the proposals which I submitted; that any comment he might be disposed to make would be only in the nature of a personal opinion; that only the House of Delegates is in a position to commit the Association. He enclosed certain principles adopted by the House in June 1944.

In all discussions of the Wagner-Murray-Dingell bill by the House of Delegates, Dr. West said, it has been clearly evident that the members think "federalization of medical service" or "the subjection of medicine to political domination" would result in deterioration of quality and in lowering professional standards. Since the bill does not propose "federalization of medical service" or "the subjection of medicine to political domination," this was not pertinent or very helpful. Dr. West then said he was forwarding a copy of my letter to various elected officers and members of official bodies of the Association (whom he listed). In the five months which followed, prior to May 24, when the bill was introduced, neither Dr. West nor any other officer of the Association submitted any comments nor was there any indication on the part of the officers of the Association of a willingness to consult with me or my colleagues.

(This portion of letter was submitted to Dr. Olin West, Secretary of the American Medical Association, who replies:)

To the Editor:—On Dec. 11, 1944 I received a letter from Senator Wagner in which it was stated that he had received numerous suggestions for changes and broadening of the health insurance provisions of the Wagner-Murray-Dingell bill. There was submitted in the letter "a list of the most important suggestions I have received." The final paragraph of Mr. Wagner's letter read as follows: "I should appreciate having your comments on these suggestions as soon as possible, preferably within the next ten days."

In my reply I informed Mr. Wagner that I did not feel that I was in a position to enter into a discussion "of the proposals for changing and broadening the health provisions of the Wagner-Murray-Dingell bill," since any comment that I might be disposed to offer would be purely in the nature of personal opinion. I stated that the House of Delegates of the American Medical Association is its policy making body and that only the House of Delegates is in a position to commit the American Medical Association with respect to legislation of such great importance to the public and to the medical profession as the Wagner-Murray-Dingell bill. I further stated that in the discussions of the Wagner-Murray-Dingell bill at meetings of the House of Delegates previously held it had been clearly evident that the members of that body, representing fifty-four constituent state and territorial medical associations, were convinced that federalization of medical service in the United States or the subjection of medicine to political domination would result in bringing about deterioration of the quality of medical service and would lower professional standards which the American Medical Association for nearly one hundred years has attempted to establish and maintain on the highest possible plane.

I informed Mr. Wagner that a copy of his letter addressed to me had been sent to the elected officers of the Association, to the members of the Board of Trustees and to the members of the Council on Medical Service and Public Relations. I sent Mr. Wagner a copy of the principles adopted by the House of Delegates of the American Medical Association in June 1944. It did not occur to me that Mr. Wagner intended that his letter to me should be considered as a request for a statement representing the policy of the American Medical Association, and even had I believed his letter to be of that nature I should not have presumed to speak for the Association. The letter merely asked for comments on certain proposals, it did not suggest or invite a conference.

Olin West.

(Senator Wagner continues:)

On numerous occasions over the past ten years the American Medical Association has been urged to put forward constructive proposals to deal with admitted needs for health and medical services in the United States. In 1934, while members of the American Medical Association staff were working with the government's staff, even before a government report could be made, the Association called a special meeting of the House of Delegates and adopted policies condemning health insurance proposals *before* they were made. In 1938 at the National Health Conference the President of the American Medical Association promised the cooperation of the Association; but no constructive proposals were forthcoming. Since then—up to the introduction of the Hill-Burton hospital construction bill—the Association has condemned every proposal which had a chance to deal with our large national needs on an adequate basis.

I say this not in criticism or to rake over old ashes, but only to point out that there is a long record of attempts to cooperate with the Association and that those who have made such attempts have always been met with rebuffs. Nevertheless, let me repeat the assurance that I am willing—as I always have been—to consult with the Association at any time.

Comment.—Senator Wagner and the representatives of the Social Security Board have queer ideas of consultation and cooperation. From the first they have insisted on federal compulsory sickness insurance as the only answer to the problem of medical care. They refuse to listen to any other proposals or to modify in any way the proposals developed through the Social Security Board and introduced by the Senator.—*Ed.*

(Senator Wagner continues:)

Your editorial disparages the importance of two medical groups which consulted with me. One group, the Physicians' Forum, you dismiss with the charge that they are several hundred physicians "mostly inclined toward communism!" This brings to mind your editorial of Dec. 3, 1932 condemning the Majority Report of the Committee on the Costs of Medical Care as "socialism and communism—inciting to revolution." This charge was made about a report—mainly recommending *voluntary* health insurance—which was prepared under the chairmanship of Dr. Ray Lyman Wilbur, president of Leland Stanford University and a former President of the American Medical Association. At the time he signed the report, Dr. Wilbur was Secretary of the Interior in President Hoover's cabinet.

Comment.*—The American Medical Association through its House of Delegates has repeatedly shown its willingness to modify its point of view by accepting various technics for spreading the costs of medical service, such as hospitalization insurance, insurance against catastrophic illness and even insurance against illness in toto. Apparently the House of Delegates has only required the submission of actual evidence based on trial that such technics represented sound insurance practice and were conducted along lines which would insure a high quality of medical service without destroying those factors essential for maintaining medical advancement. This is in contrast with the proposals of Senator Wagner, which have invariably demanded that the entire nation be placed at one time under a single system and that system always a federal compulsory sickness insurance system.—*Ed.

(Senator Wagner continues:)

Your editorial says that our bill "would take over the proposals of the Hill-Burton bill for hospital and health center construction and make of it a ten year program at ten times the cost. This is long term planning with a vengeance, in view of the experimental character of the proposal, at best." The facts, as any one can verify by reading the bill, are as follows: The Hill-Burton bill authorizes the appropriation of $100,000,000 for construction purposes during the first fiscal year; our bill proposes one half as much, or $50,000,000, for the first year. The Hill-Burton bill authorizes that there be appropriated for each fiscal year thereafter a sum sufficient to carry out the purpose. This means an authorization of an unlimited amount for an unlimited number of years. Our bill, on the other hand, authorizes a *maximum* of $100,000,000 a year only for each of the nine years after the first year. Thus, your statement about our bill was totally incorrect.

Comment.*—The most significant factor in the Hill-Burton bill is its proposal to grant funds only on demonstration of existing need and on the ability of the community to maintain a high quality of medical service under local administration and control. Grants are made only to the limit of existing needs. The Wagner-Murray-Dingell bill, 1945 version, authorizes a maximum of $100,000 000 a year for nine years. How many instances are there in which federal agencies with an authorized maximum of $100,000,000 for spending have failed to utilize the maximum?—*Ed.

(Senator Wagner continues:)

In the same paragraph you say that the new Wagner-Murray-Dingell bill also proposes to extend the grants for the venereal disease and tuberculosis programs. No such extension is contained in our bill. On these two programs our bill merely repeats the existing provisions of section 314 of the Public Health Service Act with only such editorial changes as were necessary to make clear that our proposals for expanded public health work do not change the venereal disease and the tuberculosis programs.

Comment.*—Conceivably continuous improvement in the attack on venereal disease and on tuberculosis will lessen the total expenditures required for these purposes. Is it necessary then to extend existing grants indefinitely?—*Ed.

(Senator Wagner continues:)

Your editorial makes extensive use of questions raised by an editorial on our bill in the New York *Times* for May 26. How many times have I seen your columns inveigh against the views and comments on health programs advocated by the editorial columns of that newspaper! More important, however, it is unfortunate that you fall into the same errors as the *Times*. One would gather from your comment that an unemployed worker under our proposals would only have to appear at an office and demand an unemployment check. The fact is that existing unemployment insurance laws require—and our bill requires—that an unemployed worker eligible for unemployment benefits must register at an employment office each week and that he becomes entitled to benefits only if the employment service is unable to offer him suitable employment. The bill specifically provides that he is disqualified from receiving his benefits if he refuses to accept suitable employment. You also repeat the error that "the old age benefits in some instances would pay a man more for retiring than for continuing at his job." The fact is that our bill includes the 80 per cent maximum contained in the present law, and that a man cannot receive as much on retiring as he has ordinarily earned in covered employment (see page 132, line 19, of the bill).

Comment.*—Expert economists and accountants are having difficulty in interpreting the Senator's estimates and his tables. In the *Congressional Record*, May 28, 1945, page 530, he himself introduced some corrections of errors in his tables. Practically all authorities are convinced that the sums to be spent under this bill are far beyond the 8 per cent tax on the payroll that the bill proposes. This the Senator freely admits, stating that the total amount will be made up from general taxes. Referring specifically to Senator Wagner's comments in this paragraph, is it not the maximum government control over the individual to suggest that a worker will not be entitled to his benefits under unemployment insurance unless he takes a job that a federal government agency offers him? Will the workers of this country be willing to accept that type of dictation?—*Ed.

(Senator Wagner continues:)

Finally, I want to comment on the closing sentence of your editorial. You refer to "obstinacy" typical of the manner in which my colleagues and I have tried "to impose their notions regarding the care of the public health and the sick on the people of the United States." This statement appears at the close of the same paragraph which made mention of several organizations which have endorsed the bill. Many millions of people are members of those organizations, and many tens of millions of people are represented by them and their families. When they endorse legislation, is it still only the sponsors of the bill who are trying to "impose their notions?" The facts do not square with your assertion.

It is evident from the results of numerous polls and from the many thousands of letters written to me and to my colleagues that the American public is in favor of health insurance. I feel that the American Medical Association has the opportunity to render a great public service in this field. I hope that instead of pursuing a negative policy you will join with those of us who are trying to find constructive solutions to one of America's basic problems.

ROBERT F. WAGNER,
United States Senate, Washington, D. C.

Comment.—As has already been mentioned, various state and county medical associations are now participating in trials of various technics with the hope that suitable methods can be found. This is the very opposite of obstinacy. Senator Wagner and the Social Security Board, however, have never admitted any possible answer to the problem of medical care except a federal compulsory sickness insurance system. This is the apotheosis of stubbornness and obstinacy and with it a complete lack of willingness to confer, to consult or to reason.—*Ed.*

Washington Letter

(From a Special Correspondent)

June 25, 1945.

National Advisory Health Council Reviews Its Work

Present and postwar plans of various public health service divisions were reviewed at the first meeting of the National Advisory Health Council to be held since passage of the Public Health Service Act of 1944, which was called in Wilson Hall at the National Institute of Health, June 19 and 20. The council, which serves in an advisory capacity to Surgeon General Parran, also considered recommendations to meet existing conditions resulting from the war. The National Institute of Health took up extension of grants-in-aid for additional research and methods of assistance to young scientists through fellowships, and reported on the work of the institute and laboratories. The Office of the Surgeon General explained the work of the engineering division and discussed plans to have adequately trained public health personnel for the nation. Reviews were heard from the National Cancer Institute, Division of Infectious Diseases, Division of Physiology, Biologics Control Laboratory, Chemistry Laboratory, Pathology Laboratory, Zoology Laboratory and Industrial Hygiene Research Laboratory. The Bureau of Medical Services presented statements from the Division of Mental Hygiene, the Foreign Quarantine Division, the Interservice Committee for the Control of Exotic Diseases and the International Health Relations Section. Reports were also heard from the Bureau of State Services encompassing the State Relations Division, Venereal Disease Division, Tuberculosis Control Division and Public Health Nursing. Dr. Parran heads the council, which consists of Alphone R. Dochez, professor of medicine, Columbia University College of Physicians and Surgeons; Clarence C. Selby, medical consultant, General Motors, Detroit; Kenneth F. Maxcy, professor of epidemiology, School of Hygiene and Public Health, Johns Hopkins University, Baltimore; Alfred C. Reed, associate clinical professor of medicine, Stanford University School of Medicine, San Francisco; John H. Musser, professor of medicine, Tulane University of Louisiana School of Medicine, New Orleans; Henry F. Vaughan, dean, school of Public Health, University of Michigan, Ann Arbor; Harry S. Mustard, professor of public health practice, Columbia University College of Physicians and Surgeons, New York; Gordon M. Fair, professor of engineering, Harvard University, Cambridge, Mass.; Carl S. Marvel, professor of organic chemistry, University of Illinois, Urbana; William C. Rose, professor of biochemistry, Department of Chemistry, University of Illinois; Capt. T. J. Carter (MC), U.S.N., chief, division of preventive medicine and surgery, Navy Department, Washington, D. C.; Brig. Gen. Stanhope Bayne-Jones, director of the United States of America Typhus Commission, Office of the Surgeon General, Washington, D. C.; Harry W. Schoening, assistant chief, Bureau of Animal Industry, Department of Agriculture, Washington, D. C., and Asst. Surg. Gen. R. E. Dyer, director, National Institute of Health, Bethesda, Md.

Eisenhower Lauds Work of Medical Officers in War

Tribute to medical officers in the war was paid by General Eisenhower at his news conference in the Pentagon Building on his arrival in Washington last Monday. He was asked the question "Would you like to make a statement regarding the work of the medical officers in this war?" He replied "Well, the medical officer as an individual I can't say much about. I can talk about the medical service. I think the best way to measure it is the percentage of fatalities that come out of your wounded, and it has been cut more than half, less than 50 per cent what it was in the other world war. I think for a long time we were running 33 per cent, but it has been brought about, I think, largely, first, by better organization of the medical service and, second, by the addition of the sulfonamide drugs and penicillin and the use of blood plasma and whole blood. If I could reach all America there is one thing I would like to do—thank them for blood plasma and whole blood. It has been a tremendous thing. These are the things, I believe; that and one other factor—air evacuation. We have evacuated almost every one from our forward hospitals by air, and it has unquestionably saved hundreds of lives—thousands of lives."

Criticism of Overoptimistic Publicity on Amputation Cases

The Army has been accused of giving too glowing a picture in its publicity on the ease with which soldiers who have undergone amputation are fitting back into civilian life with artificial limbs. Soldiers are reported to have found that the newly designed artificial legs and arms are better than the old ones, but not a great deal better. The claim is made that the new "miracle hand" is not being made in large enough quantities and that many men are on the waiting list. Veterans are finding that it is a long tedious process to learn to use their new limbs. It is also stated that the newest developments are not satisfactory if a soldier has lost an elbow or a knee. A considerable number of men are disclosed to have become impatient with their appliances after discharge and on return home have bought other types of artificial limbs from small shops that have sprung up.

One curious outcome of all the optimistic publicity on the dexterity of amputees is the bill introduced by Senator Langer, Republican of North Dakota, to require every major league baseball club to have at least 10 per cent of men who have lost one or more limbs. In view of this situation on soldier attitude toward artificial limbs, critics say that the matter is a psychologic problem.

Slight Increase in Infantile Paralysis

With no signs of an epidemic, infantile paralysis cases have increased slightly throughout the United States. The total number of cases for the week ended June 16 was 99, which is 4 more than for the previous week and 25 more than for the same week last year. Fear of an epidemic led Texas to ask U. S. Public Health Service aid, and Dr. A. G. Gilliam was sent to Houston, where during the week of June 9 10 cases with two deaths were reported. The state's total for the week of June 9 dropped to 37 the week of June 16, and Houston had only 8 cases the following week. Since January 1 999 infantile paralysis cases have been reported in the nation, as compared with 657 in the same time in 1944.

Patenting of Earth-Dwelling Molds Related to Penicillin

Extracts from earth-dwelling molds related to penicillin are covered in patents just issued. One compound, known as actinomycin, together with a method for extracting it, is the subject of two U. S. patents assigned to Merck and Company, which pharmaceutical firm has been active in the production of

penicillin. The patent on the mold chemical, number 2,378,876, was taken out by Prof. Selman A. Waksman of Rutgers University and Dr. Harold B. Woodruff, Merck scientist. Actinomycin, as they call it, is a red substance left after a mold known as Actinomyces antibioticus has been subjected to ether extraction and the extract then evaporated. It can be chemically separated into two fractions, designated respectively A and B. Actinomycin A is stated to be powerful in its action against certain micro-organisms. The patent covering an improved method for extracting actinomycin A was number 2,378,449, issued to another Merck employee, Dr. Max Tishler.

President Proclaims National Farm Safety Week July 22-28

President Truman has proclaimed National Farm Safety week, July 22-28, to give every farm family in the country a safety check-up. Maynard H. Coe, director of the Farm Division of the National Safety Council, suggested that individuals and organizations center their attack on falls. These, he said, occur in the farm home more frequently than any other type of accident; on burns, which usually rank about second, and on educating farm workers in the proper handling of machinery, animals and firearms. Farm leaders who have pledged their cooperation include Edward S. O'Neal, president of the American Farm Bureau Federation, James G. Patton, president of the National Farmers' Union, and A. S. Goss, master of the National Grange.

General Hines Honored for Twenty-Two Years' Service to Veterans

Veterans Administrator Hines was to be honored June 26 for his twenty-two years of service to war veterans at a testimonial dinner in the Hotel Statler arranged by the Disabled American Veterans. In 1923 General Hines was appointed director of the Veterans Bureau. Since then he has served either as director of the Veterans Bureau or administrator of Veterans Affairs, which office came into being in 1930. General Hines has supervised construction of hospitals and homes involving an expenditure of approximately $180,000,000 and during his time in office has directed the disbursement of more than $15,000,000 in veterans' benefits.

The Veterans Administration now has 46,071 employees and operates ninety-four hospitals, homes and facilities and ten regional offices throughout the United States and its possessions.

World Health Decisions Hinge on New World League Charter

Authorities state that vitally important decisions concerning medical and health problems the world over hinge on the successful completion of a charter for a new world league at San Francisco. A steering committee of all conference delegation chiefs accepted the charter as pieced together by conference experts. The decision was made on May 1 that in this final plenary session there would be no discussion or statement on the substance of approved texts.

Ample Penicillin Is Reported Available Since WLB Release

Some communities report that ample supplies of penicillin are now available for those needing it, since the War Production Board released approximately 885,000,000,000 units for civilian distribution after March 15.

Capital Notes

A bill to provide $1,300,000 for improvements at the Columbia Hospital for Women, 80 year old Washington institution, will be introduced in the Senate by Senator Radcliffe, Democrat of Maryland.

Surg. Gen. Thomas Parran of the U. S. Public Health Service continues an appeal for U. S. Cadet Nurse Corps recruits "to meet civilian health needs."

Medical Legislation

MEDICAL BILLS IN CONGRESS

Penicillin

The House has passed H. R. 3266, the bill providing for the certification of batches of drugs composed wholly or partly of any kind of penicillin or any derivative thereof. This bill is similar to the existing law safeguarding the purity of insulin.

G. I. Bill of Rights

Senator Pepper, Florida, has introduced S. 1176, proposing to amend the Servicemen's Readjustment Act of 1944 with respect to the education and training of veterans. Among other changes, this bill would (1) make benefits available regardless of whether or not education was impeded, delayed, interrupted or interfered with by reason of his entrance into service; (2) remove the requirement that the educational course shall be initiated not later than two years after discharge or termination of the war; (3) remove the distinction between veterans over 25 years at the time of induction and those under this age; (4) add special provisions for qualifying veterans who wish to complete preprofessional and professional courses of education, extending the maximum benefit to seven years regardless of length of service; and (5) increase the monetary dependency benefits to veterans obtaining education.

Another bill, H. R. 3536, introduced by Representative Rankin, Mississippi, proposes to revise generally the Servicemen's Readjustment Act of 1944.

National Neuropsychiatric Institute

Senator Pepper, Florida, for himself and Senator Thomas, Utah, Senator Tunnell, Delaware, Senator Hill, Alabama, Senator Murray, Montana, Senator LaFollette, Wisconsin, and Senator Aiken, Vermont, has introduced S. 1160 to provide for, foster and aid in coordinating research relating to neuropsychiatric disorders, to provide for more effective methods of prevention, diagnosis and treatment of such disorders and to establish a National Neuropsychiatric Institute in the United States Public Health Service. The co-authors of this bill are members of a standing committee of the Senate Committee on Education and Labor which has been created to consider proposed legislation on health.

Dental Care

The Senate has passed S. 715 to provide more efficient dental care for the personnel of the United States Navy. The purpose of this bill is to reorganize the Bureau of Medicine and Surgery so as to provide for greater integrity of the dental service of the Navy. It would direct that this reorganization be consummated within six months.

The bill removing the limitation on the right to command of officers of the dental corps of the Army which limits such officers to command in that corps, S. 916, has passed the Senate and House.

Scientific Research

The House has passed H. R. 3440, proposing an appropriation not to exceed $8,000,000 for each fiscal year to enable the National Academy of Sciences, through a research board for national security consisting of representatives of the Army and of the Navy and civilians of outstanding accomplishments to provide for scientific research and advancement determined by the board to be desirable in the interest of national security.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

State Medical Election.—Dr. Henry King Wade, Hot Springs National Park, was chosen president-elect of the Arkansas Medical Society at a meeting of the council in Little Rock, April 22, and Dr. Charles A. Archer, DeQueen, was installed as president. Other officers include Drs. Richard C. Dickinson, Horatio, DeVeaux L. Owens, Harrison, and Frederick W. Hames, Pine Bluff, vice presidents, and Paul L. Mahoney, Little Rock, treasurer. Dr. William R. Brooksher, Fort Smith, secretary of the society, was chosen delegate to the American Medical Association and Dr. Edward E. Barlow, Dermott, was also chosen delegate, succeeding the late Dr. Sidney J. Wolfermann, Fort Smith.

CALIFORNIA

Executive Director Named for Physicians Service.—Mr. William M. Bowman, who has been assistant executive director in charge of the Los Angeles office of the California Physicians Service, has been appointed executive director of the state group.

Institute in Public Health Statistics.—The University of California School of Public Health and the state department of public health cooperated in an institute in public health statistics, June 18-30. The institute, which was held on the Berkeley campus, was designed to "acquaint participants with the legal and medical aspects of vital statistics, registration procedures and the simpler technics of public health statistics." Eschscholtzia L. Lucia, Ph.D., associate professor of biometry at the university, was director of the sessions.

COLORADO

Industrial Hygiene Newsletter.—The division of industrial hygiene of the University of Colorado School of Medicine, Denver, has recently begun the publication of a newsletter to serve as a clearing house for information on industrial health matters for Rocky Mountain industrial groups.

CONNECTICUT

Personal.—Dr. Robert E. Peck has resigned as director of the department of physical therapy at Grace Hospital to make his home in Dunbarton, N. H. He was guest of honor at a dinner given at the New Haven Medical Association April 28. His resignation concludes twenty-six years' association with the hospital.

First Case of Leprosy Since 1927.—On May 21 the bureau of preventable diseases of the Connecticut State Department of Health announced the discovery of the first case of leprosy in Connecticut since 1927. The patient, who was being sent back to Jamaica and who was working on a farm in Granby under the War Food Administration program, is said to have had the disease before coming to the United States.

DELAWARE

Society News.—The New Castle County Medical Society of Delaware was addressed May 15 by Dr. Sylvester W. Rennie, Wilmington, on "Thermal Burns."

State Social Hygiene Group Formed.—The Delaware State Social Hygiene Association was recently organized with Arthur D. Maybee, chairman of the Wilmington Safety Council and director of the Blue Cross Hospital Cooperative Plan, as president. Other officers include Dr. Arthur Parker Hitchens, Wilmington city health officer, Dr. Edwin Cameron, Dover, executive secretary, state board of health, and Dr. James Beebe, Lewes, vice presidents; Taggart Evans, executive secretary, Delaware Tuberculosis Association, secretary, and Pierre S. Du Pont III, treasurer.

DISTRICT OF COLUMBIA

Scientific Assembly Canceled.—The seventeenth annual scientific assembly of the Medical Society of the District of Columbia, scheduled for October 1-3, has been canceled.

IOWA

Outbreak of Ringworm of the Scalp.—On May 28 there were 235 cases of scalp ringworm reported in Davenport, according to the Davenport *Times*.

Course on Tropical Medicine.—A short course on tropical medicine will be conducted at the State University of Iowa College of Medicine, Iowa City, July 23-28, under the auspices of the state department of health.

Personal.—Dr. Max L. Durfee, health director at Iowa State Teachers College, Cedar Falls, since 1939, has resigned to accept a position as director of health service at the University of Oklahoma, Norman, effective July 1.

Physician Honored.—The Kiwanis distinguished service medal for 1944 was recently awarded to Dr. Allen C. Starry, Sioux City, for his work as director of laboratory work of the four Sioux City hospitals and as acting health director at the time of the flood in Sioux City early in the summer of 1944. The presentation of the medal was inaugurated by the Kiwanis Club in 1922, and its rule provides that no Kiwanian may accept the medal or serve on the award committee.

KANSAS

The Root Lecture.—Dr. Lewis J. Moorman, Oklahoma City, gave the annual William W. Root Lecture of the Alpha Omega Alpha Society, May 3, at the University of Kansas School of Medicine, Kansas City. His subject was "Tuberculosis and Genius."

Public Health Election.—Dr. William Fred Mayes was chosen president-elect of the Kansas Public Health Association during its meeting in Topeka, May 21-22; Paul D. Haney, director, state division of sanitation, was installed as president. Evan Wright, director, food and drug division, state board of health, is the secretary. All are in Topeka.

Changes in Health Personnel.—Recent changes among the health officers in Kansas include the transfer of Dr. Marion Friedman, Columbus, from Cherokee County to St. Louis County, Mo., Dr. John C. Ulrey, St. John, to succeed Dr. Charles S. Adams in Stafford County and Dr. Adelbert L. Suwalsky to succeed Dr. Alonzo R. Adams as city health officer of Leavenworth.——Dr. Laurence S. Nelson, Salina, has been appointed to a three year term on the Kansas State Board of Health, succeeding Dr. Gilbert A. Leslie, McDonald, who recently moved to Colorado (THE JOURNAL, March 4, p. 723). ——Dr. Clara R. Johns, Topeka, was recently appointed health officer of Johnson County.

KENTUCKY

Changes in Health Officers.—Dr. Martin H. Skaggs has resigned as health officer of Shelby County, effective June 1, to enter private practice in Taylorsville.——Dr. Edwin Bruce Underwood, Morganfield, has been appointed director of the Henderson County health department, succeeding Dr. Edwin W. Sigler (THE JOURNAL, April 28, p. 1138).

Distinguished Service Award Created.—Dr. E. Murphy Howard, Harlan, president of the Kentucky State Department of Health and past president of the state medical association, has, with the approval of the council, provided for a distinguished service medal to be given each year to the physician who represents the ideals of Kentucky medicine. The *Kentucky Medical Journal* states that this award is distinctly separate from the distinguished service medal awarded by the state medical association but will be given each year during the annual meeting of the association. The committee on award consists of Drs. Karl D. Winter, Ben W. Smock, Lillian H. South, all of Louisville, and the president and secretary of the association as ex officio members.

MASSACHUSETTS

George Bolling Dies.—Mr. George E. Bolling, who served the city of Brockton as chemist and bacteriologist for nearly fifty years, died May 20, aged 69.

Lecture Named for George Holmes.—On May 18 the New England Roentgen Ray Society created a lecture in honor of Dr. George W. Holmes, who is clinical professor of roentgenology emeritus, Harvard Medical School, Boston. The first lecture was delivered by Dr. Holmes.

Medicolegal Conference and Seminar.—The department of legal medicine of the medical schools of Harvard, Tufts College and Boston University in cooperation with the Massachusetts Medico-Legal Society will present a six day program

of lectures, conferences and demonstrations having to do with the investigation of deaths in the interests of public safety, at Harvard, October 1-6. Attendance during five of the six days of the course will be limited to fifteen persons who have registered in advance. On October 3 the program will be open to any physician, lawyer, police official or senior medical student who may care to attend. Further information may be obtained from the secretary of the Massachusetts Medico-Legal Society, 25 Shattuck Street, Boston.

Laboratories Dedicated.—The Shrewsbury Laboratories of the Worcester Foundation for Experimental Biology, Worcester, were dedicated on June 9. The foundation was incorporated in February 1944 (THE JOURNAL, May 13, 1944, p. 160) and is set up to make investigations at the discretion of its directors in the field of biologic sciences and publish the results of these investigations in scientific and medical journals so that they may become freely available to the public. Projects studied include hormone physiology, fatigue and the activity of the cortex of the adrenal gland as measured by urinary hormone excretion products, problems of human aging and cancer. The scientific work of the foundation is under the direction of Hudson Hoagland, Ph.D., and the laboratories are under Gregory G. Pincus, Sc.D.

MICHIGAN

Personal.—Dr. Willis R. Geerlings has been elected mayor of Fremont for a fourth term.—Dr. Lowell S. Selling, Detroit, has resigned as director of the psychopathic clinic of the recorder's court, a position he held for ten years.—Dr. Wilber J. M. Menke, formerly of Paris, Ill., has been chosen deputy commissioner in the state health department for the upper peninsula.

Study of Dental Caries.—Dentists of the U. S. Public Health Service are now examining 5,000 school children in Muskegon in a dental caries demonstration in which Muskegon was chosen as the control city. Grand Rapids was also selected for the demonstration, fluorine having been added to the city's drinking water. The dental records of some 28,000 school children in Grand Rapids before the fluorine was added to the city water supply have been completed. Periodic examinations will be made of school children in both cities to note any change made in the dental caries rate.

Alumni Association Honors Old Graduates.—Life memberships in the Wayne University College of Medicine Alumni Association were presented to twenty medical men at the annual dinner of the association held May 11 at the Statler Hotel, Detroit. All were graduated from the school fifty or more years ago (THE JOURNAL, May 12, p. 144). The oldest graduate honored was Dr. John A. Wessinger, for the past thirty years health officer for the city of Ann Arbor. Dr. Wessinger, who is 85 years old and still in active practice, received his diploma in 1882. Life memberships were also presented to Dr. Walter J. Cree, for many years historian of the Wayne County Medical Society, who graduated in 1883; Dr. Alfred N. Shotwell, Mount Clemens, 1884; Dr. Mortimer E. Roberts, Grand Rapids, 1889; Dr. William J. O'Reilly, Saginaw, 1890; Dr. Christian Storz, Toledo, Ohio, and Dr. Adolphus J. W. Nixon, Highland Park, both of the class of 1891; Dr. Nenian T. Shaw, Pontiac, 1892; Dr. Duncan J. McColl, Port Huron, and Dr. William H. Hoppenrath, Elwood, Ind., both graduated in 1893. Honored members of the class of 1894 included Drs. George Alexander, Pontiac; Henri Belanger, River Rouge; Alexander Thomson, Detroit, and Orlando A. Tooker, Lansing. The class of 1895 was represented by Drs. Channing W. Barrett, Chicago; Adelbert Edwards, Detroit; Thomas E. DeGurse, Marine City; Colin D. Munro and George E. Winter, both of Jackson, and Burt R. Shurly, member of the Detroit Board of Education. Dr. Clarence A. Mills, professor of experimental medicine at the University of Cincinnati College of Medicine, Cincinnati, spoke at the dinner meeting on "Climatic Imprint on Man."

MINNESOTA

Ninety Years of Age.—Dr. Thomas F. Quinby, Minneapolis, the oldest member in point of years and the oldest living ex-president of the Hennepin County Medical Society, observed his ninetieth birthday May 10. Dr. Quinby was elected to membership in the county society March 7, 1904, served as president in 1911 and became an affiliate member in 1931.

Illegal Practitioner.—On June 5 Marjorie J. Blatzheim, aged 29, Minneapolis, pleaded guilty to a charge of practicing healing without a basic science certificate. Following a sentence to a term of one year in the Minneapolis workhouse, the sentence was suspended and the defendant was placed on probation for one year. The defendant had been arrested when it was learned that she had offered to perform a criminal abortion for a fee of $200. At the time of her arrest the woman stated that she had just purchased the speculum found in her purse at a hospital supply house in Minneapolis and that she had also attempted to purchase catheters to be used in performing abortions. She stated that she had obtained the knowledge of performing criminal abortions from a Minneapolis man who has two previous convictions for felonies and who has been in the Minneapolis workhouse on two occasions in the past year for violating the medical laws of Minnesota.

NEW HAMPSHIRE

New Dean of Dartmouth Medical School.—Dr. Rolf C. Syvertsen, assistant dean of the Dartmouth Medical School, Hanover, since June 1944 and a member of the faculty since 1923, has been appointed dean of the medical school, effective July 1. He succeeds Dr. John P. Bowler, who has resigned because of pressure of his surgical work but who will continue as professor of surgery at the medical school. Dr. Syvertsen has been professor of anatomy at Dartmouth since 1938 and for many years has been secretary of the school. Dr. Bowler has served as dean since *1927*. Dr. Bowler and Dr. Syvertsen graduated at Dartmouth Medical School in 1917 and 1923 respectively. Both also graduated at Harvard Medical School, Boston, and Rush Medical College, Chicago, in 1919 and 1936 respectively.

NEW YORK

New Secretary of State Medical Board.—Dr. Jacob L. Lochner Jr., Albany, has been serving as secretary of the New York State Board of Medical Examiners since the resignation of Dr. Robert R. Hannon, Albany, who became executive officer of the state medical society.

Typhoid Traced to Carrier.—One carrier and one suspected carrier were found in a recent investigation of an outbreak of typhoid in Rochester. All 5 patients had eaten at the same restaurant in Rochester, 4 on one day and 1 two days later, but a review of the foods consumed failed to reveal any single item common to all. Practically all personnel had been employed at the restaurant for a number of years, during which time no typhoid had been traced to this source. Examination of blood and stool specimens, however, from each of these persons led to the discovery of a definite typhoid carrier and, in addition, of a suspected carrier. The definite carrier was employed in the restaurant bakery, but only 4 of the patients gave a history of having eaten bread and, according to *Health News*, it has not yet been determined exactly how she gave rise to the 5 cases, since no common food was implicated. As control measures the carrier and the suspected carrier were both relieved of their occupations and will be kept under surveillance.

New York City

License Reinstated.—The license to practice medicine in New York of Dr. Samuel G. Sisskind, Brooklyn, has been reinstated.

Personal.—Governor Dewey on May 28 reappointed Dr. George Baehr as a member of the state public health council to serve for a six year term dating from Jan. 1, 1945.—Dr. Aaron A. Karan has been appointed executive director of the Bronx Hospital. Dr. Karan has been holding a similar position at the Beth Moses Hospital, Brooklyn.

Sulfonamide Drugs Banned Without Prescription.—The city department of health on June 12 amended section 118 of the city sanitary code to prohibit the sale of sulfonamide drugs or sulfonamide-containing products for internal or external use without a prescription, according to a release from the city department of health. The ban, which becomes effective October 1, is said to have followed a recommendation by the public health relations committee of the New York Academy of Medicine and other health groups, which pointed out that sulfonamide drugs in any form could be used safely only under expert supervision and at a physician's direction.

OHIO

Dr. Lower Honored.—The distinguished service award of the Cleveland Academy of Medicine for 1945 was presented to Dr. William E. Lower, one of the founders of the Cleveland Clinic, during the academy's annual meeting, May 18. The citation accompanying the honor cited Dr. Lower as "a distinguished surgeon and practitioner who has been a con-

stant contributor to the life of Cleveland's medical profession." The citation also said that he had been a member of the academy since 1895 and had held many offices, once president, in the organization. Dr. Loyal Davis, Chicago, addressed the meeting.

Personal.—Dr. Anna M. Young on May 19 was elected to the board of directors of the Cleveland Academy of Medicine, the first woman ever to hold the position.——Dr. Richard A. Bolt has resigned as director of the Cleveland Child Health Association to assist in the organization of the new school of public health at the University of California, Berkeley, the Cleveland *Press* reported May 21.——Dr. John N. McCann, Youngstown, has been appointed to a seven year term on the state medical board, succeeding Dr. John H. Skavlem, Cincinnati, who was appointed last November to fill the unexpired term of the late Dr. Claude V. Davis, Pennsville.——Dr. James A. Doull, professor of hygiene and public health, Western Reserve University School of Medicine, Cleveland, recently went to England on a special mission.

SOUTH CAROLINA

Fifty Thousand Dollars to Care for Indigent Cancer Patients.—The senate has approved a $50,000 appropriation for hospital care for indigent cancer patients in South Carolina. According to the state medical journal the money is expected to be made available to the state board of health July 1 and represents an increase of $34,000 over last year's appropriation of $16,000. Discussing the project, the state medical journal stated that Dr. George S. T. Peeples, Columbia, director of the division of cancer control, had announced plans to resume the program, which had been repeatedly interrupted and curtailed on account of a lack of funds. The new appropriation makes available, for the first time since the program started in 1939, sufficient money for hospital care of as much as one third of the state's indigent cancer patients. The disease, which recorded 1,205 deaths in 1944, is the second leading cause of death in the state.

TEXAS

Cancer Committees.—The M. D. Anderson Hospital for Cancer Research, Houston, University of Texas, plans to launch an educational program on cancer through the creation of statewide cancer committees, it is reported.

VERMONT

University News.—Dr. George W. Thorn, Boston, addressed the Osler Clinical Society, May 15, on "Use of Concentrated Human Albumin Solution in the Treatment of Nephrosis and Cirrhosis." This was the last of a series of lectures sponsored by the undergraduate organization at the University of Vermont College of Medicine, Burlington, during the current school year.

VIRGINIA

Changes in Health Officers.—Dr. John McIver Jackson has been appointed health officer of the Norfolk-Princess Anne Health District, succeeding Dr. William B. Baily.——Dr. Glenn H. Baird has resigned as health officer of the Smyth-Washington-Bristol Health District, effective May 10, to accept a commission with the U. S. Naval Reserve.

Student Fund Memorial to Physician.—Miss Dorothy M. Strickland, Roanoke, and Daytona Beach, Fla., has established a loan fund for worthy Southern medical students as a memorial to her father, Dr. James Thomas Strickland, according to the *North Carolina Medical Journal*. For many years Dr. Strickland practiced medicine in Roanoke.

Pathologists Organized.—The Virginia Society for Pathology and Laboratory Medicine was recently organized with Dr. William E. Bray, Charlottesville, as president. Other officers include Drs. Morris B. Beecroft, Newport News, vice president and Thomas M. Peery, Alexandria, secretary-treasurer. The society will be affiliated with the Medical Society of Virginia.

Personal.—Dr. Raymond D. Kimbrough, Norfolk, has been appointed associate professor of preventive medicine and public health and associate professor of dermatology and syphilology at the Medical College of Virginia, Richmond, effective May 1. He will continue his private practice.——Dr. Hudson Mason Wingfield has resigned as physician and surgeon of the Richmond Fire Department, effective April 30.

New Officers of Cancer Foundation.—Dr. Isaac A. Bigger, Richmond, was elected president of the Virginia Cancer Foundation at a recent meeting. Dr. George Cooper Jr., Charlottesville, was elected director. Mrs. Augusta F. Jarman, Charlottesville, was reelected secretary. The Richmond *Times-Dispatch* states that the foundation has been raising funds for the past five years to care for indigent cancer patients. At a recent meeting it was voted to extend its activities to advanced cancer patients with the idea in view that beds can be found in hospitals which do not now provide space for the care of incurable cancer cases.

Special Society Elections.—Dr. Meade C. Edmunds, Petersburg, was chosen president of the Virginia Society of Ophthalmology and Otolaryngology at its twenty-sixth annual meeting in Richmond recently. Other officers include Drs. Thomas E. Hughes, Richmond, vice president and Francis H. McGovern, Danville, secretary-treasurer. Among the speakers at the meeting were Drs. Oliver E. Van Alyea, Chicago, "Management of Chronic Sinus Disease: A Critical Analysis of Modern Therapeutic Measures"; Joseph Krimsky, Charlottesville, "Hearing Aids: The Otologist's Problem," and Grady E. Clay, Atlanta, Ga., "Ophthalmoscopic Classification of Hypertensive Diseases."——New officers of the Roanoke Academy of Medicine, who will take office in October, include Drs. Thomas J. Hughes, president; Charles M. Irvin and Blanton P. Seward, vice presidents, and George S. Bourne, secretary-treasurer.

WASHINGTON

State Medical Bureau.—Mr. Ralph W. Neill, executive secretary of the Washington State Medical Association, will combine his present activities with those of state bureau manager of the State Medical Bureau, according to *Northwest Medicine*. Offices for the bureau have been established at 218 Cobb Building, Seattle, and its purpose will be to coordinate the activities of the respective county bureaus as well as to study the provision of statewide medical and hospital service contracts. Other activities will be the investigation of assuming administration of the old age assistance medical aid program, in compliance with a suggestion by the state department of social security, and expanding medical and hospital services to cover workers' families.

WISCONSIN

Dr. Thompson Resigns as Health Officer of Racine.—Dr. Ira F. Thompson has announced his resignation as commissioner of health of Racine, effective sometime in October. Dr. Thompson has been serving in the position since 1932, when he succeeded Dr. William W. Bauer, who resigned to become director of the Bureau of Health Education of the American Medical Association, Chicago.

The Helmholz Lecture.—Dr. Thomas Duckett Jones, assistant professor of medicine, Harvard Medical School, Boston, delivered the annual A. C. Helmholz Lecture at the University of Wisconsin Medical School, Madison, June 1. His subject was "Rheumatic Fever." The Helmholz lectureship was established in the medical school in 1941 by the children of Mr. and Mrs. August C. Helmholz.

Memorial to Dr. Grill.—To perpetuate the memory of Dr. John C. Grill, students, friends and associates are establishing a fund to be known as "John Grill, M.D., Memorial Fund," the interest of which is to be used to buy books for the medical library of the Marquette University School of Medicine, Milwaukee, according to the *Milwaukee Medical Times*. Dr. Grill had been associate professor of bacteriology and pathology at Marquette until December 1944, when he was made head of the department. He died March 17.

PHILIPPINE ISLANDS

Status of Medical Facilities.—A communication June 12 received from the Philippines reports the destruction by recent action of the medical school and library, the cancer hospital and the outpatient buildings at the University of the Philippines. All of the clinical records of the Philippine General Hospital, Manila, were destroyed and only a few broken test tubes and specimen jars were left in the laboratory. Members of the staff who have survived the Japanese occupation are devoting their full time to the treatment of any and all who are sick and cannot be treated at home. There is a shortage of everything, and many diagnoses are made on physical findings alone. Serologic tests are made by one of the Army laboratories. Limited blood counts are done in the hospital but bacteriologic studies are not possible at present, it was

stated. There is a great need for books and periodicals for the medical school and hospital and the library. The communication credited the great skill of the Filipino physicians in the present emergency.

GENERAL

Sixteen Air Lines Operate Without Fatalities.—Sixteen American air lines completed their 1944 operations without a single fatal accident, the National Safety Council reported June 26 in announcing its 1944 Aviation Safety Awards.

Meetings Canceled.—The 1945 meeting of the Mississippi Valley Medical Society, scheduled to be held at St. Louis in September, has been canceled because of war restrictions. Plans are being made to hold the 1946 meeting in the Jefferson Hotel, St. Louis, September 25-27.——The National Safety Congress of the National Safety Council scheduled for October will not be held this year.

Booklet Urges National Program on Nutrition.—The National Planning Association has issued a booklet entitled "A Food and Nutrition Program for the Nation" which carries a proposal that the President appoint a special committee of public officials and experts to make recommendations on government organization for nutrition. The recommendation was also made that this same group serve as the U. S. representative in the International Food and Agriculture Organization.

Trudeau Medal Goes to Florence Sabin.—At a meeting of the executive committee in New York June 6 the National Tuberculosis Association has awarded its Trudeau Medal to Dr. Florence R. Sabin, Denver, for her "extensive studies of the physiologic activities of the chemical fractions of the tubercle bacillus." Dr. John Alexander, Ann Arbor, Mich., was chosen president-elect of the American Trudeau Society, medical section of the National Tuberculosis Association, and Dr. Ezra R. Bridge, Rochester, N. Y., was inducted into the presidency.

New Committee Urges Cabinet Post for Health and Welfare Services.—A new cabinet post for education, health and welfare services will be advocated by the Committee on Reorganization of Community Services, according to the chairman, Mrs. Eugene Meyer, as reported in the New York *Times*, June 12. The committee of twenty-five working under the auspices of the Woman's Foundation plans to submit a detailed report soon, it was stated. Mrs. Meyer is reported to have said that a secretary of health, education and welfare, such as her committee proposes, would help local and state agencies by "dynamic leadership and financial assistance and by setting standards 'below which no American should be permitted to live.'"

Esmond Snell Receives Lilly Award.—Esmond E. Snell, Ph.D., of the research staff of the Clayton Biochemical Institute of the University of Texas, Austin, was on May 26 presented with the Eli Lilly and Company award in bacteriology and immunology for 1945 in recognition of his work on the nutritional requirements of micro-organisms. Selection of the recipient of the award is made by committees of the Society of American Bacteriologists, American Association of Immunologists and the American Society for Experimental Pathology. Eli Lilly and Company has made an additional grant making possible three more awards, presumably for 1946, 1947 and 1948. The award consists of a check for $1,000 and an engraved medal.

Narcotic Violations.—The U. S. Bureau of Narcotics announces the following actions:

Dr. Charles J. Raney, Yazoo City, Miss., pleaded nolo contendere to a violation of the Harrison Narcotic Law in the U. S. District Court, Jackson, Miss., May 7, and was placed on probation for three years.

Dr. James Samuel Harmon, Prichard, Ala., pleaded nolo contendere in the U. S. District Court at Mobile, Ala., to a violation of sending poison through the mail and on May 5 was sentenced to one year and one day and fined $500. Execution of the penitentiary sentence was suspended.

Dr. William Allen Young, Louisville, Miss., pleaded guilty in the U. S. District Court at Aberdeen, Miss., April 2 to violation of the narcotic law and was sentenced to a prison term of one year and one day and placed on probation for a period of five years.

Dr. Pasquale E. Massa, Boston, pleaded guilty in the U. S District Court, Boston, May 1, to violation of the Harrison Narcotic Law and was fined $500 and placed on probation for five years.

Dr. Joseph A Hirsch, Edwardsville, Ill., pleaded guilty in the U. S. District Court at Springfield, Ill., to violation of the federal narcotic law on March 19 and was fined $2,000.

Dr. Charles W. Robertson, Chandler, Okla., was fined $1,000 on April 11 following his plea of guilty in the U. S District Court at Oklahoma City to violation of the Harrison Narcotic Law.

Dr. William Lee Cosby, Painter, Va., pleaded guilty in the U. S District Court at Norfolk May 18 to violation of the Harrison Narcotic Law. He was given a suspended sentence for one year and placed on probation for a similar period.

Metropolitan's Tuberculosis Sanatorium to be Closed.—On September 1 the Metropolitan Life Insurance Company will close its tuberculosis sanatorium, which has been maintained at Mount McGregor, N. Y., since 1913 for the treatment of its tuberculous employees. Although a total of 3,507 employees have received treatment for tuberculosis since 1913, it is now felt that the number of patients and the period of treatment have been reduced to a point which no longer justifies the maintenance of an institution of this size. Patients now at the sanatorium will be given treatment at the company's expense in comparable sanatoriums located nearer to their homes. The Metropolitan sanatorium is located in the foothills of the Adirondack Mountains near Saratoga, N. Y. It occupies about 1,600 acres and consists of thirty buildings, including besides the main fireproof structure ward buildings, an infirmary and residences for the physician in charge, the staff and the nurses' home, providing facilities for the treatment of about 300 patients. One of the buildings, the John R. Hegeman Memorial Laboratory, established by the will of a former president of the Metropolitan, has been the seat of much of the modern research in the disease. The first director of the sanatorium was the late Dr. Horace J. Howk. He was succeeded by Dr. William H. Ordway, the present director.

FOREIGN

Faculty of Ophthalmologists Organized.—With the creation of a Faculty of Ophthalmologists by the Council of British Ophthalmologists, the council has dissolved. Officers of the council of the faculty were elected by ballot at its first meeting, April 12, and consisted of Brigadier Sir Stewart Duke-Elder, R. A. M. C., president; Dr. Frank A. Juler, vice president; Dr. Frank W. Law, honorary secretary, and Dr. Frederick A. Williamson-Noble, honorary treasurer. The address of the faculty is 45 Lincoln's Inn Fields, London, W. C. 2.

Endowment for Department of Anatomy.—Sir William Henry Collins, chairman of the Cerebos Salt Company, has made a gift of £100,000 to the Royal College of Surgeons for the endowment of the department of anatomy and for the establishment of a chair of human and comparative anatomy, according to *Science*. Last year Sir William gave £100,000 to endow a chair of pathology. The museum and research departments have been damaged during the war. Their maintenance, however, is now assured by the gift, and the college can proceed with its rebuilding plans.

Laboratory to Conserve Pathogenic Microbes.—A laboratory has been established in Lausanne, Switzerland, under the sponsorship of the Swiss Academy for Medical Sciences, which specializes in the preparation and conservation of pathogenic microbes common to man, animals and plants and which will operate in connection with the Institute of Hygiene and Bacteriology. Dr. Paul Hauduroy, professor of medical sciences at Lausanne and director of the Institute of Hygiene and Bacteriology, has been appointed director. According to an announcement from the Official Information Bureau of Switzerland, New York, samples of various microbes will be sent to scientists in all parts of the world who need such specimens in their research work. A detailed catalogue of the samples available will be prepared.

Japs Maintain Quinine Production in the Netherlands Indies.—Dr. Pieter Honig, member of the board for the Netherlands Indies, who recently returned from a survey of the liberated section of the Indies, stated that his observations and last minute underground reports show that the Japanese have been maintaining all quinine producing equipment that were not destroyed by the Dutch early in 1942. Dr. Honig is quoted in the Netherlands *News* as saying that reports coming from the men on the occupied islands indicates that quinine in the form in which the Dutch processed it is steadily being produced by the enemy to fight malaria and further that no Dutch or Indonesians are getting the quinine even though some of the equipment was left intact for that purpose. Much new equipment for processing cinchona bark into quinine, including twenty-five huge drying ovens capable of producing 2,200 pounds of dried bark per oven daily, is being purchased in the United States as rapidly as possible. This new machinery, plus vast numbers of trees maturing whenever the Indies are freed, will result in greatly increased quinine production for fighting global malaria, Dr. Honig said. He pointed out that, because cinchona trees from which quinine is extracted mature in cycles, no acute shortage of either bark or drug can occur for about fifteen years. By that time, authorities believe, the gap caused by Japanese omission to plant new trees will be closed by other means.

May 26, 1945.

The British Medical Journal During the War

In its annual report the council of the British Medical Association states that the *Journal* has continued to appear regularly notwithstanding the war difficulties of production and distribution, with severe rationing of paper and shortage of staff. Since last year's report the obligatory circulation has grown in consequence of a large increase in membership, and the weekly printing order now approaches 53,000. With that figure a journal with an overall size of 60 pages and sometimes 64, compared with an average of 144 in 1938, can be produced on the present paper ration. Every means of economizing space has been adopted. From the early part of 1942 circulation outside the membership has been drastically curtailed and new subscriptions will be declined as long as the paper shortage remains. The number of original articles and medical memoranda submitted are far in excess of the space available under wartime conditions. Last year 946 signed articles were received, compared with 801, 797, 737 and 667 in the preceding years of the war. The total is now as large as before the war. Of the large number of letters from members at home and abroad only a selection can be published. The new section "Any Questions?" begun in 1943 has established its popularity and is continued in response to a wide demand. A first selection of the questions and answers has been prepared for publication in book form but awaits an allowance of paper for the purpose. A projected *Journal of Social Medicine,* under the editorship of Prof. F. A. E. Crew, to be issued by the association, is held up for the same reason.

Schemes for Emigration to the Dominions

The Japanese attempt to dominate the countries on the Pacific has wakened Australia and New Zealand to the danger of a small white population in control of vast territory in proximity to hundreds of millions of Asiatics. Hence immigration from Europe, preferably from Britain, has become important. Mr. F. M. Forde, deputy prime minister of Australia, who went to the San Francisco conference by way of London, stated that Australia had plans for the absorption of a steady flow of immigrants. The aim is to treble the present population of 7,300,000 in the shortest possible time. The extent to which the government succeeds would help substantially in ensuring the future security of the Pacific. Tens of thousands of emigrants from the British fighting forces would be welcomed, and it was hoped that the thousands of the young men now serving with the British fleet in the Pacific would make their homes in Australia after the war. They had decided on a child emigration scheme of 17,000 a year for three years after the war. Children from Britain would be preferred, but it was felt that the scheme should be extended to European children.

Daily inquiries at the London offices of the dominions in the last few months show an even more widespread desire to emigrate than in the closing stages of the last war and after it. The stream of inquirers includes civilians in many callings and members of the forces—skilled and unskilled, men and women—professional men in search of wider scope and careers for their children, parents wishing to rejoin sons and daughters, and others anxious to find places where their assured incomes would offer most benefits. But the available shipping is an obstacle. Australia House is receiving 700 to 800 inquiries a week. The New Zealand Office receives about 500 applications a week. South Africa House receives some 600 inquiries a week. Canada House is unable at present to discuss any plans for emigration, as Canada is already dealing with a large transport problem. Many thousands of Canadian soldiers who have served in this country have married British women. Already a special department deals with applications for the passage of wives and children at the rate of 100 a day. It is expected that the final total will be between 25,000 and 30,000. The difficulty which confronts all schemes of emigration to the dominions is, as previously shown in THE JOURNAL, that we are deeply concerned as to the maintenance of our population in Britain in consequence of the fall of the birth rate. The Australian scheme for child emigration is based on the large number of war orphans. On the European continent children have lost parents not only in the fighting but under the atrocious Nazi rule, with its deportations. Their parents have simply disappeared.

A College of Speech Therapists

A new institution, a College of Speech Therapists, has been formed. At the inaugural session Sir Farquhar Buzzard, who presided, said that over many years he had become more and more aware of the value of speech therapists to the doctor. He believed that the comprehensive medical service, now proposed, cannot function completely owing to the shortage of doctors, and that difficulties must be met by making greater use of medical auxiliaries, including speech therapists.

A surgeon, Mr. Zachary Cope, who is president of the Board of Registration of Medical Auxiliaries, said that none of the universities have a professor or lecturer in speech therapy. He thought that local authorities should regard speech as at least as important as grammar. Nine out of ten doctors, if asked where they would send a patient with defective speech, would be unable to give an answer. As an examiner in surgery he had known many candidates who might have failed owing to a speech defect but for an effort at understanding by the examiner. He thought that there should be a speech therapist at all major hospitals, but outside London there were only twenty-five hospitals with a speech therapist attached to them. At present the new college had only 200 to 300 members, but twice or thrice that number were needed.

A Record in Blood Donation

The Ministry of Health has published what it calls "a new record for blood donations." In the course of a single day's session a mobile team operating from the ministry's blood transfusion center at Leeds collected blood from 820 donors, all of whom were service personnel at a military unit. This is the highest number of donors ever dealt with by one team during a working day. The team consisted of one medical officer assisted by twelve nurses, a blood grouping technician and a clerk. They worked from 8 a. m. to 4:30 p. m. The next day all the blood collected was flown to the British army in western Europe.

Physician's Bequest for Carrying Out the Treatment He Advocated

Dr. J. R. Whitwell, for twenty-seven years medical superintendent of St. Audry's Hospital, Melton, Suffolk, has left his fortune of $130,000 to form a fund for the after-treatment of the mental patients of his hospital and to help to set them up in occupations. He always contended that many discharged mental patients could again become useful citizens if financial help was provided for them. Thus his bequest provides for the carrying out of the treatment he advocated during his life.

A Register of Dietitians

The Board of Registration of Medical Auxiliaries has published the first register of dietitians, which contains the names of 140 members of the British Dietetic Association. Dietetics is defined as "the interpretation and application of the scientific principles of nutrition in health and disease." But registered

dietitians agree, in cases of disease, not to undertake the dietetic treatment of any condition except under the direct control of a registered medical practitioner. The register is designed for the use of those requiring the services of an expert on all matters pertaining to diet.

Exhibition of War Injuries

An exhibition of war injuries is being held at the Royal Society of Medicine. Open only to the medical profession, it consists of pathologic specimens, colored photographs and drawings of typical war injuries. Before its destruction by German bombs the Army Medical War Collection was housed at the Royal College of Surgeons. The Medical Research Council then arranged with other medical organizations for a new collection, some of which is now being shown.

Mortality in France Since the War

The reports of the Institut national d'hygiène, published by its director, Professor Chevallier, brought out a peculiar mortality trend since the war, which consists in a considerable increase in the mortality in some areas but is compensated in part by a less pronounced and unexpected reduction in mortality figures in other regions. The zones with increased mortality are the densely populated regions; the zones with a decrease are predominantly rural regions with a developed agriculture.

Mortality rates in a homogeneous, chiefly agricultural region formed by nine departments in the west with a population of 4,183,000 for 1937, 1938 and 1939 amounted to 59,316, or 170 for 10,000 inhabitants; in the course of the three war years 1941, 1942 and 1943 the death rate here averaged only 152 for 10,000 inhabitants, a decrease of 10.6 per cent. In an urban region located on the Mediterranean with a population of 5,872,000 there were during the period from 1936 to 1938 an average of 53,176 deaths, a mortality rate of 137 per 10,000 of population, and for 1941 to 1943 a rate of 188 per 10,000, an increase of 37.2 per cent.

This tendency to increase in deaths in urban populations and to decrease in rural regions was found over the entire territory. The causes of this difference are difficult to determine, but it seems that nutrition plays an important part. Lack of conveyances and difficulties in distribution were doubtless responsible for the cruel want in the cities.

Considering the mortality by age groups and comparing it in the two typical regions selected by Chevallier, it was found that in the rural regions the decrease is general except in infants under 1 year, in whom the death rate has increased on the average by 22 per cent. In the urban regions the deaths of infants under 1 year have increased by 14 per cent, but the general mortality showed a growing curve with an almost normal profile, attaining 185 in aged persons. The decrease in mortality in the agricultural region involves particularly the active part of the population, between 15 and 65 years. It seems that for this population the war conditions have brought an improvement in living conditions; their diet permits them to endure their hard work better. In the Mediterranean or urban region the picture is bleak because of the increase in mortality in the ages usually affected by tuberculosis. It is, in fact, 28 per cent between the ages of 30 and 35.

The dietetic conditions before the war were not satisfactory in the rural regions. Different observers have noted that as a result of the occupation (refusal to deliver their produce, difficulties of communications), the French farmers have themselves consumed considerable quantities of the rich foods which they formerly sold, such as meat, butter and eggs.

Mortality of Infants During the Winter of 1944-1945

In 1938 the mortality of infants under 12 months diminished slowly but constantly, but in 1940 the mortality increased by 40 per cent; 1941 brought a mild improvement in the rate, with a decrease of 12 per cent, and in 1942 by 7.4 per cent as compared with 1938. The great increase in 1940 was due in part to the exodus, which was hard on the very young. However, in 1943 the ratio between 1938 had risen again by 15 per cent, without there being important epidemics during this year. The maximum number of deaths in 1943 occurred in the months of July and August, when before the war the mortality curve would show a slight fall. At the same time there was a renewed increase in the disorders of the digestive tract. The poor quality of the milk was probably the chief cause of the increase in infant mortality. The infants of 1944, except for the lucky ones who received American shipments of condensed milk, drank the worst milk. In 1941 the Germans imposed a decree requiring a skimming of 30 per thousand. Objections of pediatricians and hygienists were in vain; and this measure, designed to increase the requisitions of butter by the occupants, led to regrettable manipulation such as mixing skimmed and whole milk, as well as other adulterations. Furthermore, as Lesné has pointed out in a report to the Académie de médecine, war conditions led to a weakening of milk control. It was poorly

TABLE 1.—*Mortality in Paris During the Past Two Winters*

Months	Deaths in Paris	Months	Deaths in Paris	Excess
December 1943	151	December 1944	354	203
January 1944	169	January 1945	576	407
February 1944	194	February 1945	552	358

TABLE 2.—*Average Weight of the Newborn in France*

Years	1938	1939	1940	1941	1942	1943
Weight in grams	3,277	3,262	3,255	3,166	3,135	3,232

pasteurized, and the milk cans were inadequately cleaned because of lack of fuel. The milk soured easily and contained several million germs per cubic centimeter, with thousands of bacilli of the coliform type.

The situation was aggravated in 1944 and the rigors of the winter have been fatal for nurslings. The comparative figures for the winter of 1944-1945 and the preceding one are given in table 1.

The weight is not the essential measure of the vitality of an infant. If it has not suffered an intrauterine infection, the weight of a child will remain normal or almost normal whatever the state of the health of the mother. Even a cachectic tuberculous mother will have a fully developed child. One can see this from the average weights of the infants born during the war years (table 2) of mothers debilitated and depressed by malnutrition, anguish, hard work and prolonged standing.

The severe and prolonged winter and lack of fuel was largely responsible for the deaths of the newborn, whom the war conditions made more susceptible. They succumbed chiefly to upper respiratory or pulmonary disorders.

There is fear that in the coming summer there will be a considerable increase in the deaths of the very young from gastrointestinal disturbances because of the poor quality of the milk. To save these children France needs large quantities of canned milk. It is hoped that the energetic measures considered by the health services will at least attenuate this grave danger. There arrive now daily in Paris 60,000 liters of bottled milk which is pure, wholesome and up to the old standards. These shipments will increase considerably in the coming months.

ICELAND

May 25, 1945.

Nutrition of the Population

A committee was appointed by the government in 1939 to obtain information on the nutrition of the Icelandic population, which, although unquestionably greatly improving, was suspected of being in some respects deficient. No fruits are grown in the country, and production of cabbage is relatively small. The staple diet has for a long time been fish, mutton, milk, potatoes and bread.

INVESTIGATION OF FAMILY DIETS

Although a shortage of vitamin C must be expected under these conditions, scurvy has been a rare disease in this century. Formerly one of the worst scourges of the country, it has dwindled to insignificance since consumption of potatoes came into common usage about one hundred and fifty years ago. The lack of sunshine during the dark winter months must lead to a deficiency of vitamin D, and rickets is a common ailment, although rarely encountered in its worst form. A systematic survey of children under 2 years of age showed an incidence of 74 per cent with clinical or roentgenologic signs of rickets.

The first task of the National Council of Nutrition was to have an investigation made of what people were eating in Iceland. For that purpose sixty-five families were selected to keep careful records of their diets for a whole year. Of these fifty-four made satisfactory records, but nine were omitted as unreliable. These fifty-four families from different parts of the country supplied the information from which Dr. J. Sigurjónsson compiled his data on the food consumption of the population, as published in his monograph Mataræði og heilsufar (Reykjavik, 1943).

MAIN CHARACTERISTICS OF NUTRITION

The average consumption of men was found to be 3,090 calories in towns and villages and 3,553 calories among the rural population. Seasonal variations were negligible. Protein consumption averaged 135 Gm. per day in towns and villages and 167 in the country, or from three to four times what Sherman considers should be the minimum. As 70 Gm. is considered sufficient for everybody, the people are consuming twice that amount. The source of this liberal protein consumption is chiefly to be sought in fish and milk, both of which are abundantly available all over the country. Fat consumption was 125 and 155 Gm. respectively in towns and the country, contributing about 40 per cent to the total calory consumption. Carbohydrates contributed a similar amount to the calory intake, or 330-350 Gm. per day. The intake of calcium varied from 0.68 to 2.95 Gm. per day, averaging 1.14 in towns and 2.08 in the country. The liberal calcium intake is probably at least partially deprived of its nutritional value through lack of vitamin D. The Ca/P ratio was 1/1.5-1.68 in towns and 1/1.3-1.4 in the country, or fairly well balanced. The intake of iron was sufficient, 18 to 28 mg. per day. The chief characteristic of the average food consumption is seen to be the high protein intake, which is higher than found elsewhere (Denmark 110, Cardiff 78.7, Sweden 99 Gm., all prewar figures).

VITAMINS

The intake of vitamin A varied from 1,386 international units in a town in spring to 6,151 in a rural community in autumn. All communities showed lowest intakes in spring and highest in autumn. Most communities ranged between 2,400 and 3,000 international units per day.

Vitamin D is a difficult factor to grasp in such a survey, as the skin irradiation cannot be estimated. The low content of this vitamin in the food (generally from 100 to 300 international units) indicates a deficient supply of this important food factor in a country where everybody lacks sunshine in winter and the greater part of the population does not take the required advantage of the long days in summer. This vitamin may therefore with certainty be considered as insufficiently supplied in most homes.

Vitamin B_1 was considered fairly sufficient, averaging 446 international units in rural areas and 569 in towns. Riboflavin and niacin were not estimated, nor the rest of the B complex.

The intake of vitamin C varied from 12.5 mg. per person daily in spring in towns to 50.2 mg. in rural areas in autumn, the usual intake being about 20 mg. per adult. One community was down to 7.2 mg. in spring.

The chief sources of vitamin C are milk and potatoes, neither of which is rich in ascorbic acid. The content of potatoes decreases on storage, so that potatoes are a poor source in spring, which is clearly reflected in the figures from all places.

In spite of the low intake in this vitamin, scurvy is a rare disease in Iceland, only a few cases being observed yearly. The question whether latent scurvy is frequent cannot be answered at present, but many doctors incline toward the opinion that in spite of the low intake there is no visible lack in this vitamin. It has long been known that some people need more of this vitamin than others, and the possibility cannot be rejected that a selection has taken place through ages of hardship, with extermination of those requiring the higher quantities. Yet the constant hunger for fruits among the population points to an unsatisfied demand, which may have a deeper cause than that of novelty and change. As clinical signs of scurvy do not appear until four to six months after deprivation of the vitamin, there might exist a latent scurvy in winter and spring, which is corrected by consumption of fresh vegetables in summer.

EFFECT ON HEALTH

Icelanders in general have bad teeth, probably owing to lack of vitamins C and D, both of which are necessary for normal odontoblastic function. The increased requirements of women in the childbearing period is reflected in the caries rate. Up to 16 years the women have better teeth than men, but after that their teeth deteriorate much more rapidly. In the age group 30-40 the men displayed a caries rate of 31 per cent, but 90 per cent of all teeth in the examined women were decayed in this age group.

Tuberculosis has for a long time been a devastating disease in Iceland, the mortality rate surpassing 200 per hundred thousand a decade ago. The great proportion of acute cases, caseous pneumonia, meningitis and miliary dissemination is supposed to be a result of faulty nutrition, chiefly with regard to vitamins C and D. The fact that hepatic cirrhosis (Laënnec's) is hardly ever seen in Iceland might be explained by the protein-rich nutrition, which gives a good protection against damage to the liver.

Marriages

WINDER LAIRD PORTER, Wilmington, Del., to Miss Gladys Virginia Streett of Harbeson, May 12.

JOHN R. TIMMONS, Columbia, S. C., to DR. FRANCES WOODS LOVEJOY in Scarsdale, N. Y., June 2.

RICHARD S. O'CONNELL, Poston, Ariz., to Miss Virginia Bayliss of Rohwer, Ark., recently.

CARLTON L. OULD, San Francisco, to Miss Ruth McKevitt of Ironwood, Mich, January 6.

WILLIAM HENRY FOEGE to Miss Leslie Warnick Phelps, both of New York, June 3.

THOMAS J. RITTER to Miss Mary Susan Kern, both of Allentown, Pa., April 23.

MAJOR BERNARD WINKLER to DR. MIRIAM F. HELLER, both of Brooklyn, May 10.

JOHN T. SULLIVAN JR. to DR. TULLIA D. TESAURO, both of Chicago, May 30.

Deaths

Beverley Randolph Tucker ⊕ Richmond, Va.; Medical College of Virginia, Richmond, 1905; since 1938 emeritus professor of neuropsychiatry at his alma mater; specialist certified by the American Board of Psychiatry and Neurology, Inc.; past president of the Tri-State Medical Association and the Mental Hygiene Society of Virginia; president of the Richmond Academy of Medicine, 1942-1943; member of the American Neurological Association and the American Psychiatric Association; fellow of the American College of Physicians; member of the Society of Cincinnati, serving as president in the state of Virginia from 1933 to 1935; member of the state board of health and chairman of the first governor's Mental Advisory Board at the state penitentiary; during World War I member of the medical advisory board in Virginia, and contract surgeon in the U. S. Army in 1918; member of the American board of the American Hospital in Paris; member of the board of Nemours Foundation; served as vice chairman of the city library board; member of the board of the Industrial Home for Girls and consulting physician to State Colony for Feebleminded and Epileptic; neuropsychiatrist to the hospital division of the Medical College of Virginia; first Juvenile Court physician and one of the founders of the children's clinic; consulting neuropsychiatrist to the Johnston-Willis and St. Elizabeth's hospitals; editor, *Old Dominion Journal of Medicine and Surgery* from 1908 to 1914; author of "S. Weir Mitchell" 1914, "Nervous Children" 1916, "Verses of Virginia" 1923, "The Lost Lenore" (one act play) 1929, "The Gift of Genius, Adolescence" 1930, "Narna Darrell" 1936, "Various Verse" 1938, "Tales of the Tuckers" 1942; author of the section on cranial nerves in Tice's Practice of Medicine; contributed articles to medical publications and poems to newspapers and magazines; founder of the Tucker Hospital, where he died June 19, aged 71, of cerebral thrombosis.

John Edward Jennings, Brooklyn; Columbia University College of Physicians and Surgeons, New York, 1899; member of the American Medical Association, serving in the House of Delegates in 1931; past president of the Medical Society of the County of Kings; member of the American Surgical Society; member of the New York Academy of Medicine; a fellow of the Brooklyn and New York Surgical societies, the New York Gastroenterological Society and the Brooklyn Thoracic Society; a fellow and founder member of the American College of Surgeons, serving as a member of the board of governors from 1926 to 1941 and regent since 1931 and first president of the Brooklyn chapter; specialist certified by the American Board of Surgery; at one time clinical professor of surgery at the Long Island College Hospital; during World War I entered the medical corps of the U. S. Army as a major and was promoted to lieutenant colonel in charge of an evacuation hospital in France; during World War II acted in an advisory capacity on the Selective Service staff; member of the New York City Board of Health; attending surgeon, St. Peter's Hospital; surgeon in chief, St. John's Hospital; consulting surgeon, Huntington (N. Y.) Hospital and the Mary Immaculate Hospital, Jamaica, N. Y., Bethany Deaconess, Beth-El and Cumberland hospitals, Norwegian Lutheran Deaconesses' Home and Hospital and the Brooklyn Hebrew Home and Hospital for Aged; consulting surgeon and formerly director of the surgical service, Brooklyn Cancer Institute; senior surgeon at the Brooklyn Hospital, where he died May 25, aged 69.

Frederick Bingham Miner ⊕ Flint, Mich.; Detroit College of Medicine, 1906; specialist certified by the American Board of Pediatrics, Inc.; fellow of the American Academy of Pediatrics and the American College of Physicians; member of the American Public Health Association and at one time chairman of its committee on endemic goiter; member of the Detroit Pediatric Society and the Michigan Trudeau Society; past president of the Genesee County Medical Society, which he served for many years as treasurer and business manager, becoming in 1914 the first editor of its *Bulletin*; a captain in the medical corps of the U. S. Army during World War I; one of the organizers of the pediatric section of the Michigan State Medical Society; served as examiner for the Kiwanis Health Camp, examiner of Civil War veterans, executive board member and past president of the Genesee County Tuberculosis Association, secretary of the medical advisory board of the Clara Elizabeth Fund for Maternal Health and president of the Donald McFarlan Whaley Memorial Home for Children; formerly physician for the King's Daughters Home; on the Mayor's Health Committee and the boards of the International Institute and Family Service Agency; formerly director of pediatrics at Hurley Hospital; at the time of his death in charge of pediatrics at the Women's Hospital and St. Joseph Hospital; for three years a member of the Oak Grove Hospital; a trustee and at one time vice president of the Michigan State Horticultural Society; died April 26, aged 68, of myocardial infarction.

Hilliard Eve Miller ⊕ New Orleans, Tulane University of Louisiana School of Medicine, New Orleans, 1916; joined the faculty of his alma mater on Nov. 12, 1917 as assistant instructor in obstetrics and gynecology and shortly thereafter was made instructor in clinical obstetrics; on July 13, 1925 appointed instructor in clinical gynecology and in July two years later made assistant professor of gynecology, professor of gynecology and head of the department from July 1, 1936 until he resigned July 16, 1944; served on the faculty of the Graduate School of Medicine of Tulane University; fellow of the American Gynecological Society, of which he had been secretary and member of the council; fellow of the American College of Surgeons and the Southern Surgical Association; member of the Southeastern Surgical Congress, Southern Medical Association and Louisiana State Gynecological and Obstetrical Society; member and in 1926 president of the New Orleans Gynecological and Obstetrical Society; a first lieutenant in the medical corps of the U. S. Army during World War I; served as chief of the department of gynecology at the Touro Infirmary, senior gynecologist in the Tulane Division of the Charity Hospital and consulting gynecologist at the Flint Goodridge Hospital of Dillard University; trustee of the Isaac Delgado Memorial Fund; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; wrote chapters for Curtis's Obstetrics and Gynecology and Davis's Obstetrics and Gynecology; died April 20, aged 51, of heart disease.

James Howell Corwin, Washington, Pa.; Jefferson Medical College of Philadelphia, 1903; member of the American Medical Association and member of its House of Delegates in 1934, 1942 and 1943; past president of the Washington County Medical Society; past vice president of the Jefferson Medical College Alumni Association; member of the committee on medical economics of the Medical Society of the State of Pennsylvania; city medical director of Washington; on the staff of the Washington Hospital; died in the Veterans Administration Facility, Aspinwall, May 20, aged 66, of arteriosclerosis and diabetes mellitus.

John Pracher ⊕ Monroe, La.; Georgetown University School of Medicine, Washington, D. C., 1915; member of the American Society of Clinical Pathologists; served as assistant professor of anatomy (histology and embryology) at his alma mater and instructor in biology in the dental school; formerly on the staff of the Tuberculosis Hospital in Washington, D. C., and clinical pathologist at the Holy Family Hospital in La Porte, Ind.; since July 1927 clinical pathologist and bacteriologist at St. Francis' Sanitarium; died March 30, aged 62, of coronary occlusion.

Braden Miller Alleman ⊕ Cincinnati; Eclectic Medical College, Cincinnati, 1929; served during World War I; secretary-treasurer of the staff and member of the consulting and active staff of the Bethesda Hospital; died May 10, aged 47, of coronary disease.

George Shafter Allen, Baltimore; Howard University College of Medicine, Washington, D. C., 1924; died March 27, aged 46, of cerebral hemorrhage.

Edwin Judge Barnett ⊕ Spokane, Wash.; University of Illinois College of Medicine, Chicago, 1916; member of the American Academy of Pediatrics; specialist certified by the American Board of Pediatrics, Inc.; served overseas during World War I; interned at the Cook County Hospital in Chicago; on the staffs of the Deaconess, Sacred Heart and St. Luke's hospitals; died March 29, aged 50, of coronary thrombosis.

Martin L. Barshinger ⊕ York, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1893; formerly health officer of York; served as physician to the County Home and city jail; died April 9, aged 78, of carcinoma of the prostate.

Harry Ferris Beebe, Grayslake, Ill.; Chicago Homeopathic Medical College, 1894; formerly health officer of Antioch and president of the school board; died May 17, aged 78, of heart disease.

Harry Franklin Bennett, Litchfield, Ill.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1895; member of the American Medical Association; for many years secretary of the Montgomery County Medical Society; served during World War I; died in St. Francis Hospital May 18, aged 73, of cerebral hemorrhage.

Raymond Joseph Blum ⊕ Rochester, N. Y.; University of Buffalo School of Medicine, 1910; on the staff of St. Mary's Hospital, where he died May 22, aged 57, of carcinoma of the lung.

Barbara Jean Boyd, San Francisco; University of Oregon Medical School, Portland, 1942; interned and served a residency at the Children's Hospital, where she died April 29, aged 28, of injuries received in an automobile accident.

William Griffiths Carter Brannon, Philadelphia; Howard University College of Medicine, Washington, D. C., 1918; member of the American Medical Association; on the courtesy staff and formerly chief of the outpatient department and associate in the department of surgery at the Frederick Douglass Memorial Hospital, where he died April 8, aged 51, of hemiplegia due to hypertensive cardiovascular disease.

Fidelio Fletcher Brown, Chicago; National Medical College, Chicago, 1896; Dunham Medical College, Chicago, 1900; also a dentist; life member of the Illinois Dental Association and member of the American Dental Association; died May 28, aged 75, of cardiac degeneration and Parkinson's disease.

Lee Van Leer Brown, De Land, Fla.; University of Pennsylvania Department of Medicine, Philadelphia, 1902; member of the American Medical Association; past president of the Volusia County Medical Society; served overseas during World War I; served on the staff of the Deland Memorial Hospital; died March 20, aged 65, of arteriosclerosis.

Edward A. Bruns, Plymouth, Wis.; Homeopathic Medical College of Missouri, St. Louis, 1899; died March 12, aged 72, of coronary thrombosis and arteriosclerotic heart disease.

Walter Edward Bundy, Oak Hill, W. Va.; University College of Medicine, Richmond, 1908; member of the American Medical Association; president of the Fayette County Medical Society; died June 4, aged 61, of heart disease.

William Craig Byers ⊕ Webster, Pa.; Medical Department of the Western University of Pennsylvania, Pittsburgh, 1906; served during World War I; associate staff member of the Charleroi-Monessen Hospital, Charleroi, where he died April 28, aged 74, of cerebral hemorrhage.

Jesse Hope Campbell, Commerce, Ga.; Emory University School of Medicine, Atlanta, 1916; member of the American Medical Association; fellow of the American College of Surgeons; specialist certified by the American Board of Otolaryngology; served during World War I; on the staff of the Commerce Hospital; died April 14, aged 54, of angina pectoris.

William Taylor Chamberlin ⊕ Hempstead, N. Y.; Hahnemann Medical College and Hospital of Philadelphia, 1898; served as mayor of Hempstead and as president of the village; physician to the Nassau County Home; on the staff of the Nassau Hospital, Mineola; died May 22, aged 71, of pneumonia.

Thomas Grier Cook, Nicholasville, Ky.; Medical College of Virginia, Richmond, 1903; member of the American Medical Association; formerly coroner of Jessamine County; on the courtesy staffs of St. Joseph's Hospital and Good Samaritan Hospital, Lexington, where he died May 12, aged 72, of arteriosclerotic and congestive heart disease and cerebral hemorrhage.

William Alva Davis, Baltimore; Baltimore Medical College, 1898; member of the Society of American Bacteriologists; died March 28, aged 70, of carcinoma of the stomach.

William Henry Earnest, Seymour, Iowa; Cincinnati College of Medicine and Surgery, 1870; Civil War veteran; died March 4, aged 96, of coronary thrombosis.

Ottice Norval Eisaman, Pittsburgh; Medical Department of the Western University of Pennsylvania, Pittsburgh, 1906; director of the division of biologic laboratory, city board of health; in 1918 appointed bacteriologist; died April 19, aged 71, of cerebral hemorrhage and myocarditis.

MAJOR EDGAR CRAWFORD FONDE, M. C., A. U. S., 1905-1945

LIEUT. COMDR. GEORGE W. FOX, (MC), U.S.N.R., 1906-1945

Charles Bennett Fisher, Washington, D. C.; Howard University College of Medicine, Washington, 1918; died June 3, aged 54, of carcinoma of the prostate.

Horace Lee Franks ⊕ Baltimore; College of Physicians and Surgeons, Baltimore, 1892; died April 2, aged 77.

Paul W. Friedemann, Stillwater, Okla. (licensed in Oklahoma by years of practice); a commissioned officer, served six years in the Imperial Russian Army; member of the American Medical Association; on the staff of the Stillwater Municipal Hospital; member of the chamber of commerce; died March 15, aged 84, of coronary thrombosis.

John Archibald Garrettson ⊕ Indianapolis; Medical College of Indiana, Indianapolis, 1904; a medical officer during World War I; for many years a member of the faculty of his

KILLED IN ACTION

Edgar Crawford Fonde ⊕ Mobile, Ala.; University of Pennsylvania School of Medicine, Philadelphia, 1930; interned at the Pennsylvania Hospital in Philadelphia and served a residency at the Presbyterian Hospital in San Juan, P. R.; began active duty as a captain in the medical corps, Army of the United States, on Aug. 22, 1942; assigned to the Lawson General Hospital in Atlanta, Ga.; later went to the Mayo Clinic, Rochester, Minn., then for a six weeks course at the Army Medical School, Walter Reed Hospital, Washington, D. C.; assigned to the Kennedy General Hospital in Memphis, Tenn., for a short while; went overseas in February 1945, at which time was reassigned to the surgical division of the 106th Evacuation Hospital; from D day on through the invasion in command of a field surgical unit and worked behind the advancing lines through France and across the Rhine; promoted to major; killed in action north of Frankfort, Germany April 1, aged 39.

George William Fox ⊕ Milwaukee; Rush Medical College, Chicago, 1931; interned at the Presbyterian Hospital in Chicago; member of the Milwaukee Academy of Medicine and the American Association of Railroad Surgeons; specialist certified by the American Board of Surgery; served as clinical instructor in surgery at the Marquette University School of Medicine and on the staffs of the Milwaukee Children's and Milwaukee hospitals; at one time chief surgeon for the International Harvester Company; held the position of assistant surgeon with two railroad firms; began active duty as a lieutenant in the medical corps of the U. S. Naval Reserve on Aug. 17, 1942; later promoted to lieutenant commander; died during attack on the *Franklin* in the Pacific area March 19, aged 38, of asphyxiation.

alma mater; served on the staffs of the City, St. Vincent's and Methodist Hospitals; died April 20, aged 66, of cardiovascular renal disease.

William Priest Greening ⊕ Pauls Valley, Okla.; Hospital College of Medicine, Louisville, Ky., 1901; served during World War I; on the staff of the Lindsey-Johnson-Shirley Hospital; died March 2, aged 69, of coronary thrombosis.

William Greig, Denver; Bellevue Hospital Medical College, New York, 1881; member of the American Medical Association; died in the Mount Airy Sanitarium March 22, aged 92, of lobar pneumonia.

Hovhanness Manook Hadidian ⊕ Troy, N. Y.; American University Medical School, Beirut, Syria, 1905; served during World War I; on the courtesy staff of the Samaritan Hospital; died May 19, aged 67, of coronary thrombosis.

Russell Lowe Hodge ⊕ North Kansas City, Mo.; Chicago College of Medicine and Surgery, 1912; served during World War I; on the staff of the Research Hospital, Kansas City, where he died March 27, aged 57, of carcinoma of the transverse colon.

Robert Elias Hogan, Dallas, Texas; Birmingham Medical College, 1901; member of the American Medical Association and the Medical Association of the State of Alabama; veteran of the Spanish-American War; died March 18, aged 69.

Francis Joseph Lennon, Buffalo; University and Bellevue Hospital Medical College, New York, 1908; served during World War I; on the staff of the Millard Fillmore Hospital, where he died April 24, aged 57, of ruptured esophageal varix.

Charles W. Littlefield, Seattle; Kansas City (Mo.) Homeopathic Medical College, 1896; died February 24, aged 85, of senility.

John Julius Loomis, Durango, Colo.; Loyola University School of Medicine, Chicago, 1922; member of the American Medical Association and the Nebraska State Medical Association; interned at St. Mary of Nazareth Hospital, Chicago; on the staff of St. Elizabeth's Hospital and for twelve years chairman of the department of obstetrics at the Bryan Memorial Hospital, both of Lincoln, Neb.; died March 21, aged 51, of coronary disease.

COLONEL JARRETT M. HUDDLESTON, M. C., U. S. A., 1893-1944

CAPT. PAUL LINTON KISTNER, M. C., A. U. S., 1916-1944

John Hortmon Mathews, Rebecca, Ga.; Birmingham Medical College, 1915; died March 27, aged 59, of coronary thrombosis.

John Adams Metzger, Long Beach, Calif.; University of Pennsylvania Department of Medicine, Philadelphia, 1896; served in the U. S. Army from 1898 to 1905; placed on the reserve list as a major in 1908; formerly instructor and lecturer at the University of Southern California School of Medicine in Los Angeles; died May 9, aged 72, of cardiovascular heart disease.

Harry Maurice Montgomery, Burlington, N. C.; North Carolina Medical College, Davidson, 1903; member of the American Medical Association and honorary member of the Medical Society of the State of North Carolina; died March 31, aged 73, of angina pectoris.

James Lida Montgomery, Ellamore, W. Va.; Maryland Medical College, Baltimore, 1908; died in Baltimore, Md., April 7, aged 61, of coronary thrombosis and arteriosclerotic cardiovascular disease.

Harrison Galmoree Morris, Baton Rouge, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1900; member of the American Medical Association; past president of the Tangipahoa Parish Medical Society; on the associate staff of Our Lady of the Lake Sanitarium, where he died March 21, aged 79, of bronchopneumonia and coronary occlusion.

Harold Louis Walden ⊕ Corbin, Ky.; University of Louisville Medical Department, 1921; died March 2, aged 48.

Raymond Delbert Watson ⊕ Britton, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1929; physician for draft board number 7; on the staffs of the Polyclinic Hospital, University Hospital and the Wesley Hospital, Oklahoma City, where he died March 14, aged 40, of uremia.

Charles H. Wheeler, Okolona, Miss.; Meharry Medical College, Nashville, Tenn., 1907; died February 26, aged 67, of cerebral hemorrhage.

Giovanni Zoilo, Brooklyn; Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1905; on the staff of the Cumberland Hospital; died February 2, aged 66, of heart disease.

KILLED IN ACTION

Jarrett Matthew Huddleston ⊕ Colonel, M. C., U. S. Army, Washington, D. C.; George Washington University School of Medicine, Washington, 1916; Medical Field Service School, Carlisle Barracks, Pa., in 1921, the Army Medical School, Washington, D. C. in 1922 and the School of Aviation Medicine, Mitchel Field, N. Y., in 1923; commissioned a first lieutenant in the medical reserve corps of the U. S. Army in 1917; appointed to the regular army in October 1918; rose through the various ranks to that of lieutenant colonel in 1937; later promoted to colonel; during World War I served overseas as regimental surgeon with the First Engineers, First Division, was in six major engagements and received the Croix de Guerre for bravery; after the signing of the Armistice was assigned to the Army of Occupation; formerly professor of military science and tactics at George Washington University School of Medicine and the Georgetown University School of Medicine; served as secretary of the Army Medical School; in March 1942 assigned to duty at Headquarters, Second Army, then detailed to the 7th Corps, Allied Forces Headquarters, Algiers, and later joined the Fifth Army; awarded the Legion of Merit and an Oak Leaf Cluster to the Silver Star posthumously; a U. S. Army Hospital Ship named in his honor; before leaving for his last assignment overseas was stationed at Fort Beauregard, La.; in action since the landing of the troops in Salerno until he was killed Feb. 9, 1944, aged 51.

Paul Linton Kistner, St. Louis; St. Louis University School of Medicine, 1942; interned at St. John's Hospital; entered the medical corps, Army of the United States, on June 2, 1942; began active duty as a first lieutenant on July 3, 1943; promoted to captain; assistant regimental surgeon, 106th Infantry, 423d Regiment; killed Dec. 23, 1944, aged 28, while a prisoner of the Germans subsequent to the battle of the Bulge.

Correspondence

TREATMENT OF ERYTHROBLASTOSIS FETALIS

To the Editor:—The opinions expressed by Dr. Ruth Darrow on the treatment of erythroblastosis fetalis (THE JOURNAL, April 28, p. 1146) are so greatly at variance with present concepts of this disease and its pathogenesis that we of the Blood Grouping Laboratory in Boston wish to draw your attention to certain proved facts concerning Rh sensitization and its recognition, together with the observations of many investigators on the best therapeutic procedures for the treatment of erythroblastotic infants.

It is an accepted fact that the Rh positive erythrocyte has antigenic properties capable of stimulating Rh antibodies in an Rh negative person. The antigen may enter the body either directly by transfusion or via the placenta. Agglutinating antibodies (Rh agglutinins) resulting from such sensitization may be demonstrated by the proper laboratory methods as emphasized repeatedly by Levine and by Wiener. In some cases the severity of erythroblastosis in the infant appears to be directly proportional to the titer of such agglutinins in the maternal blood; in other instances, however, there is little or no agglutinin demonstrable by the usual technic (incubation of a 2 per cent suspension of Rh positive cells with the unknown serum for thirty to sixty minutes) and these cases in general have the most severe manifestations of the disease. The explanation of this paradox was furnished by Race, by Wiener and by Diamond and Abelson, who proved beyond doubt that inhibitor or blocking antibody is present in such instances and interferes with the usual laboratory technic for agglutination of Rh positive cells. The last mentioned writers also found that these inhibitor antibodies are most commonly present and tend to increase in concentration after repeated stimulation, thus being associated with progressively more severe erythroblastosis in successive infants. In the experience of the Blood Grouping Laboratory there is a close correlation between this evidence of repeated stimulation (i. e., blocking antibody) and the most serious forms of erythroblastosis such as icterus gravis, fetal hydrops and intrauterine death.

Dr. Darrow's statement that "sensitization does not parallel the number of antibodies either in the blood or in the body tissues" reveals an apparent unfamiliarity with this blocking phenomenon, which represents greater, rather than less, sensitization and certainly does not suggest immunity in the sense of desensitization. On the contrary, it has been demonstrated that with the proper tests for recognition of blocking antibodies in the blood (and these tests are very easily and simply applied) (Diamond and Abelson: *J. Lab. & Clin. Med.*, March 1945) the level of antibody does parallel the degree of sensitization and the severity of the disease in the infant. With respect to determination of antibody titers in body tissues, we know at present of no method of making either qualitative or quantitative estimations of such antibodies.

Attention is drawn next to that section of Dr. Darrow's letter dealing with the actual effects of anti-Rh agglutinins on the infant. The liver, lungs, spleen and other tissues are involved beyond question. However, the changes in these organs are, in the opinion of most pathologists, the result of the severe hemoclastic effect of the antibody-antigen reaction. Splenomegaly and hepatomegaly vary directly with the degree of red cell destruction and regeneration; pulmonary involvement, purpuric hemorrhages, edema and other findings are manifestations of very severe and frequently terminal hemolysis associated with blocking of end capillaries with cellular débris. In view of this the degree of anemia, rapidity of its onset and progress appear to provide the most reliable criterion for the institution of proper therapeutic measures rather than such indefinite signs as "toxicity." In the opinion of two well known investigators in this field (Mollison, Gimson) "the most important single clinical feature is the progressive fall in hemoglobin level below that normally expected." Furthermore, our experience with those cases manifesting cerebral damage (kernicterus) demonstrates that all such cases occur in those severely jaundiced infants who represent an extreme degree of sensitization of the mother, and not in those infants manifesting anemia without icterus.

The use of Rh positive blood transfusions in the treatment of erythroblastotic infants to prevent "flooding of the circulatory system with an excess of erythrocytes, since the Rh positive cells absorb the antibodies and are destroyed," seems to us an illogical procedure, especially since there is adequate proof that Rh negative cells not only replace the destroyed erythrocytes of the erythroblastotic infant but, in addition, survive. On the contrary, transfused Rh positive cells are totally destroyed within three days. Evidence of the superiority of Rh negative over Rh positive blood has come from workers in Great Britain, Canada and South America as well as from workers in this country. It seems, therefore, unsound to advocate the introduction of Rh positive cells, since the cellular débris resulting from their certain destruction may embarrass an already overburdened infant's system. Certainly such a rationale is not indicated by the experience of consultants in hematology who deal with hemolytic diseases in all ages.

The administration of oxygen is undoubtedly of value in the presence of anoxic anoxia; on the other hand, transfusion of viable erythrocytes seems the appropriate therapeutic approach to the problem of anemic anoxia. In our experience intravenous glucose and saline solutions are not usually indicated as they tend to aggravate the edema and further embarrass the circulation. The multiple syringe method of transfusion is often a more difficult method than gravity or a simple gravity plus pressure set for tiny infants with poor peripheral veins.

Finally, the statement is made that early delivery of infants with probable erythroblastosis is ineffectual. Though it is certainly not desirable to impose too great prematurity on such a child, there is no doubt that two to four weeks of prematurity is a much slighter risk than the same period of time spent by the fetus in an environment where an increasing antibody absorption from the mother's circulation may produce more severe damage to the erythrocytes and secondarily to other important systems of the body. Statistics gained in the study of more than thirty families in which a previous child has succumbed to erythroblastosis support the opinion that earlier delivery of the next infant, especially in the face of an increasing antibody production on the part of the mother, results in a larger number of living children recovering from the disease. This occurs in spite of the well known increasing chances for more severe involvement of the infant born to the mother who has been sensitized by earlier pregnancies.

LOUIS K. DIAMOND, M.D.
RONALD L. DENTON, M.D.
Boston.

To the Editor:—In the communication on the treatment of erythroblastosis fetalis in THE JOURNAL, April 28, Dr. Ruth Renter Darrow emphasized certain aspects of the condition which have been neglected. It is conceivable that, in cases in which an Rh negative donor cannot be found, Rh positive blood, given slowly and under constant observation to an erythroblas-

totic child, may be the lesser evil as compared to no transfusion. So far as these cases go, her statement that no infant should die while Rh negative blood donors are being sought may be a useful antidote to excessive and inflexible dogmatism on the need for Rh negative donors.

However, situations in which the use of Rh positive blood is justified would seem to be exceedingly rare. In view of the existence of much misapprehension about the mechanism of erythroblastosis due to Rh incompatibility, it is perhaps more necessary at present to emphasize the importance of making every effort to find Rh negative donors.

Furthermore, one may question the advisability of using Rh positive blood "by preference, because of its sparing action on the infant's red cells." The author also states that "with Rh positive blood there is no danger . . . of flooding the circulatory system with an excess of erythrocytes, since the Rh positive cells absorbing the isoantibodies are destroyed."

The harm done by transfusions in which the injected cells are destroyed is not, as would seem to be implied by the author's statements, entirely or principally due to deprivation of the destroyed cells. The most serious dangers from destruction of transfused red cells are (1) kidney damage due to hematin precipitated from the dissolved hemoglobin freed by hemolysis of the transfused cells and (2) thrombosis of capillaries by agglutinated red cells or their stromas. This damage may be fatal or, if the patient survives, may leave irreversible lesions. Hence the hypothetic "sparing action on the infant's red cells" is far more than counterbalanced by the amply demonstrated dangers of intravascular hemolysis.

It is also questionable that "a 'toxic' baby with a red cell count of 4,000,000 per cubic millimeter of blood is therefore in far greater need of an immediate transfusion than a nontoxic baby with a count of 2,000,000." If the baby with a count of 4,000,000 is in a state of oligemic shock, plasma would be the indicated treatment in preference to whole blood, while the child with a count of 2,000,000 red cells would in most cases be in urgent need of replacement of the lost red blood cells with Rh negative cells resistant to hemolysis by the anti-Rh agglutinins in the child's plasma. The mother's blood cells can be used, provided they are separated from the plasma and are of a compatible group.

A. F. LIBER, M.D., Amsterdam, N. Y.
Director, Montgomery County Laboratory.

PSYCHOPATHOLOGY AND TERMINOLOGY

To the Editor:—There is a lamentable tendency in current psychiatry to use the label constitutional psychopathic inferior almost with complete abandon. It seems that in many instances it even becomes a means of projecting on the victim of the diagnosis the prejudices and inferiorities of the psychiatrist.

The very term C. P. I. implies a condition or state from birth, and yet many are so labeled who have never manifested any form of inadequacy until past maturity.

Dr. W. C. Alvarez in his article Constitutional Inadequacy in THE JOURNAL, July 4, 1942, page 782, column 2, lines 25 to 27, states that "like the walls of a defective tire they are likely to hold well for some time before they blow out."

No histologic, biologic or psychodynamic basis is given for this comparison of the human being to a tire.

But what is more important than the lack of basis for the statement is the fact that here we have a prominent psychiatrist finally pinning the label "constitutional inadequacy" on the psychoneuroses. Here is an example of psychotherapeutic defeatism given the dignity of a respectable paternity.

Quoting further, he states that "in some cases poor materials seem to have gone into almost every organ of the body," which again places all the emphasis on the individual's constitutional equipment.

Yet psychiatry has demonstrated that such conditions as chronic delinquency and chronic criminality can be eliminated at their ontogenetic sources. Certainly the neurosis, a much less profound and less inrooted condition, can be approached prophylactically as well as therapeutically.

To advise these patients to "hoard their energies and find a job that can be done without too much fatigue" is, in fact, to increase their feelings of inadequacy, frustration and insecurity, and encourage a chronic invalid attitude which is the very thing that should be avoided psychotherapeutically. It also discourages any efforts on the part of society to seek the elimination of the causes of these disorders and ignores the numerous instruments of therapeusis, from psychoanalysis to personal readjustments.

Further, no one who has followed the psychically ill can fail to observe how often just the elimination of a chronic focus of infection will achieve the complete psychic restitution of the individual. Often, simply the modification of external factors will do it.

Heredity, of course, is important, very important, but we have seen numerous examples of individuals with excellent inherited factors finally break down into neurosis because of overwhelming ontogenetic traumas. On the other hand, there are numerous instances of bad hereditary factors submerged and completely inactivated by the combination of a favorable environment and the felicitous course of events.

It is therefore evident that the neurosis is too dynamic, has too many interrelated causative and influencing factors and is too complex in its very nature to justify its being swept into the dumping ground of constitutional inadequacy.

Such a term is too general and devoid of psychiatric structure, as well as an injustice to the psychically ill.

MYER E. SEGAL, M.D.
State of Connecticut Veterans Home,
Rockey Hill, Conn.

BENIGN PNEUMONOCONIOSIS

To the Editor:—In our paper on Benign Pneumonoconiosis (THE JOURNAL, March 24, p. 701) there appears the statement that "advanced silicosis with conglomerate nodulation is often a disabling disease, and when silicosis is complicated by tuberculosis it is fatal." In the summary we state that "advanced silicosis is usually disabling and, when complicated with tuberculosis, it is fatal."

The statement that advanced silicosis when complicated with tuberculosis is fatal has been questioned, and properly so, because there are many patients with advanced silicosis who have inactive pulmonary tuberculosis without pronounced disability. We mean, of course, that advanced silicosis is fatal when complicated by active, progressive pulmonary tuberculosis.

WRITE TO A BOY IN SERVICE

To the Editor:—At the suggestion of several pharmaceutical representatives who have called at the office I wish to report a little venture that my associates and I have made in our waiting room. We have a little stand on which are stamped V-Mail and pen and ink with a small sign inviting our patients to write a letter to a boy in service while waiting for their turn to see the doctor.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Right of Physician in Kentucky to Receive Fee from County for Executing and Filing Birth or Death Certificate.—The treasurer of Bell County, Ky., questioned his legal right to pay (1) physicians or midwives in attendance at the birth of a child a fee of 25 cents for each birth certificate that they executed and filed as required by statute or (2) physicians the same fee for each death certificate made and filed by them. The applicable Kentucky statute reads in part as follows:

"Each local registrar, physician or registered midwife shall be entitled to be paid the sum of twenty-five cents for each birth certificate and each death certificate properly and completely made out and registered with or reported by him, and correctly copied and duly returned to the Division of Vital Statistics. . . . All amounts payable to registrars, physicians or midwives under this section shall be paid by the treasurer of the county in which the registration districts are located, upon certification by the Division of Vital Statistics. The Division of Vital Statistics shall annually certify to the treasurers of the several counties the number of births and deaths registered, with the names of the local registrars and the amounts due each at the rates fixed herein." (K R S sec. 213.150.)

Thirty physicians of that county instituted an action against the county treasurer seeking an injunction to require him to pay them such fees. From a judgment for the physicians the county treasurer appealed to the Court of Appeals of Kentucky.

The sole question to be determined here, said the appellate court, is whether a comma in the statute quoted should be regarded as the word "and." As noted, the statute specifically provides *"Each local registrar, physician or registered midwife shall be entitled to be paid the sum of twenty-five cents for each birth certificate and each death certificate properly and completely made out and registered"* in accordance with the terms of the statute. Literally the statute provides for the payment to only one of the three classes, the comma in such disjunctive clauses ordinarily taking the place of "or." The original statute was an Act of 1910 (chapter 37, sec. 20) and was in the same form. The difficulty here is not one of punctuation, which is ordinarily a minor element in construing a statute. The question is whether the word "and" should connect "registrar" and "physician or registered midwife." Not the literal language but the true intention or will of the legislature is the law. That is what the courts endeavor to ascertain and declare and what the executive departments must obey. All rules of statutory construction have that in view. Since words are used to express an idea, if that idea is manifest, although ineptly or obscurely expressed, no usurpation is committed by declaring the legislative intent and no violence done by supplying, deleting or changing words or their arrangement in clarification. The general intent is the key to each part of an act. Often its purpose and its entire tenor disclose the inadvertent or careless misuse or omission of a word or phrase, and the courts are justified in correcting or supplying the proper language. As stated in Lewis' Sutherland on Statutory Construction, section 397:

The popular use of "or" and "and" is so loose and so frequently inaccurate that it has infected statutory enactments. While they are not treated as interchangeable, and should be followed when their accurate reading does not render the sense dubious, their strict meaning is more readily departed from than that of other words, and one read in place of the other in deference to the meaning of the context.

The statute before us, continued the court, imposes the duty on either the physician attending a birth or the midwife, as the case may be, of making out the certificate and filing it with the registrar. On the face of it, it cannot be supposed that he or she should receive no compensation for this public service, which is basic and more laborious than the duty imposed on the registrar, who simply records the certificate and advises the state registrar. It is to be noted that the fee is payable "for" each certificate "properly and completely made out and registered." The registrar does not execute certificates of this sort. If there were no intention that the physician or midwife, who is charged with the duty of making out the certificates, should be paid, the natural inquiry arises Why should they have been mentioned at all? On the other hand, why should the Division of Vital Statistics be required to certify to the county treasurer each year the names of the registrar only? The case in which the constitutionality of the original act was declared involved the decision that a local registrar is entitled to collect this fee from the county. *Furlong* v. *Darnaby*, 206 Ky. 63, 257 S. W. 707; second appeal, *Darnaby* v. *Furlong*, 216 Ky. 475, 287 S. W. 913. As between conflicting consequences, a statute will be construed so as to make it equitable and just rather than inequitable and unjust. It would have been unjust not to provide compensation for the physician or midwife for making out the certificate but to provide payment of the one who records it. The same section, K R S 213.150, expressly declares that none of those persons can charge "any member of a family in which a birth or death may occur" for such services.

We cannot escape the conclusion that the trouble arises in this case, said the court, from mere faulty formulation of the phrase, and that the comma was inadvertently or intended to be used instead of the word "and." Therefore the trial court rightly construed the statute to provide that both the local registrar and the physician are entitled to have the county treasurer pay them the stipulated fees. If a registered midwife has performed the service of the physician, she should receive the fee.

The judgment in favor of the physicians was accordingly affirmed.—*Asher, Treasurer, v. Stacy, 185 S. W. (2d) 958 (Kentucky, 1945).*

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and Examining Boards in Specialties were published in THE JOURNAL, June 23, page 614.

BOARDS OF MEDICAL EXAMINERS

ALASKA: Juneau, September. Sec., Dr. W. M. Whitehead, Box 561, Juneau.

ARIZONA:* Phoenix, July 5-6. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

CALIFORNIA: *Oral.* Los Angeles, Aug. 11. *Written.* San Francisco, July 9-12. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento 14.

CONNECTICUT:* *Homeopathic.* New Haven, July 10-11. Sec., Dr. J. H. Evans, 1488 Chapel St., New Haven. *Medical. Examination.* New Haven, July 10-11. *Endorsement.* New Haven, July 24. Sec. to the Board, Dr. Creighton Barker, 258 Church St., New Haven.

DELAWARE: *Examination.* Dover, July 10-12. *Reciprocity.* Dover, July 17. Sec., Medical Council of Delaware, Dr. J. S. McDaniel, 229 S. State St., Dover.

IDAHO: Boise, July 10. Dir., Bureau of Occupational Licenses, Miss Agnes Barnhart, 355 State Capitol Bldg., Boise.

INDIANA: Indianapolis, Aug. 28-30. Sec., Board of Medical Registration & Examination, Dr. W. C. Moore, 301 State House, Indianapolis 4.

MAINE: Augusta, July 10-11. Sec., Board of Registration of Medicine, Dr. A. P. Leighton, 192 State St., Portland.

MASSACHUSETTS: Boston, July 10-13. Sec., Board of Registration in Medicine, Dr. H. Q. Gallupe, 413-F. State House, Boston.

MONTANA: Helena, Oct. 1-3. Sec., Dr. O. G. Klein, First Nat'l. Bank Bldg., Helena.

NEVADA: *Reciprocity.* Carson City, Aug. 6. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

NEW MEXICO:* Santa Fe, Oct. 8-9. Sec., Dr. LeGrand Ward, 141 Palace Ave., Santa Fe.

NORTH DAKOTA: Grand Forks, July 3. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OHIO: *Endorsement.* Columbus, July. Sec. Dr. H. M. Platter, 21 W. Broad St., Columbus.

OREGON:* Portland, July 25-27. Exec. Sec., Miss L. M. Conlee, 608 Failing Bldg., Portland 4.

PENNSYLVANIA: Philadelphia and Pittsburgh, July 10-13. Act. Sec., Bureau of Professional Licensing, Department of Public Instruction, Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

RHODE ISLAND:* July 5-6. Chief, Division of Examiners, Mr. Thomas Casey, 366 State Office Bldg., Providence.

SOUTH DAKOTA:* Pierre, July 17-18. Sec., Medical Licensure, State Board of Health, Dr. Gilbert Cottam, State Capitol, Pierre.

TEXAS: Houston, July 17-19. Sec., Dr. T. J. Crowe, 918-20 Texas Bank Bldg., Dallas 2.

WASHINGTON:* Seattle, July 16-18. Sec., Department of Licenses, Miss Nell Adams, Olympia.

WEST VIRGINIA: Charleston, July 5-7. Commissioner, Public Health Council, Dr. John E. Offner, State Capitol, Charleston 5.

* Basic Science Certificate required.

MICHIGAN: Ann Arbor and Detroit, Oct. 12-13. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing.

NEBRASKA: Omaha, Oct. 2-3. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Bldg., Lincoln 9.

OREGON: Portland, July 7. Sec., Mr. C. D. Byrne, University of Oregon, Eugene.

RHODE ISLAND: Providence, Aug. 15. Chief, Division of Examiners, Mr. Thomas Casey, 366 State Office Bldg., Providence.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Vitamin Content of Liver Extracts for Parenteral Use: Comparison of Crude and Concentrated Preparations. G. W. Clark.—p. 520.

"Modified Globin" from Erythrocytes as Plasma Substitute.—Strumia and his associates prepared a globin from human erythrocytes which can serve as a plasma substitute, because it possesses some of the properties of plasma, more specifically a high colloidal osmotic pressure. It is estimated that every year nearly 1.5 billion cubic centimeters of packed red cells may be made available from the preparation of plasma for the armed forces and for the civilian population. By a relatively simple process this hemoglobin can be transformed into a "modified globin." From the amount of red cells mentioned 375,000 Kg. of globin can be prepared with an osmotic power about twice as great as an equivalent amount of plasma proteins, that is, an osmotic equivalent of about 12.5 million liters of citrated plasma. From a blood donation it is possible to obtain about 250 cc. of plasma and about 24 Gm. of globin. This globin is equivalent in osmotic power to about 600 cc. of plasma. Thus from a single 500 cc. donation of blood it is possible to obtain the osmotic equivalent of about four donations. Modified globin is safe and capable of replacing lost blood volume in cases of severe secondary shock. A total of 210 intravenous injections of globin have been administered to 108 human beings. The largest single dose has been 57 Gm. The largest total amount administered to any one patient has been 192 Gm. Several patients have received repeated injections of globin without exhibiting reactions.

Acute Myocarditis with Influenza A Infections.—A woman aged 34 who in December 1942 had a mild illness that might be construed as clinical influenza became acutely ill early in April 1943 and died in six days. The fatal illness was accompanied by fever, chills, extreme prostration and progressive dyspnea. There was evidence of myocardial weakness, and diffuse signs appeared in the lung bases before death. Clinically the findings were interpreted as those of a rapidly progressing primary atypical pneumonia. Necropsy revealed a minimum of pathologic alterations in the lungs, but the heart showed an extreme degree of acute diffuse myocarditis. Isolation of a virus from the lungs of this patient and its identification as influenza A makes it a very unusual case. It led to further search for similar cardiac lesions in other cases of influenza. A second patient, a man aged 39, presented the aspects of an acutely fatal pneumonia complicating influenza A. The virus obtained from the lungs showed characteristic lesions of a virus infection. The lesions in the heart were slight and limited in extent and were discovered only after careful search. They were similar in character to those seen in the first case. Finland and his associates believe that the myocardial lesions in these cases are the result of infection with influenza A virus.

Intravenous Bismuth Sodium Tartrate in Tularemia.—In the past three years Jackson has observed 61 cases of tularemia from Arkansas, Oklahoma, Missouri, Kansas, Louisiana and Texas. In 57 cases the source of infection was a tick bite; 1 was a squirrel bite; 3 were hand infections acquired by skinning rabbits. Every patient with tularemic tick bite on the lower extremity developed a bubo on the corresponding side. Two presented lesions on the penis, 1 an ulcer on the dorsal corona, the other an ulcer on the anterior surface at the base of the shaft. One of these developed a right-sided bubo, the other a left-sided one. Twenty-one cases with lesions on the arms or upper torso all showed an axillary adenitis, but in only 2 did the nodes progress to suppuration. No reason is apparent as to why the inguinal lymph nodes break down and the axillary do not. Epitrochlear lymph nodes suppurated in 2 cases in which the forearm presented the initial lesion. The initial chill and malaise occurred between seventy-two and one hundred and twenty hours after discovery of the tick and its removal from the skin. Agglutination tests were done in all cases. All but 2 showed positive titers of 1:360 or over. Jackson's experience with the Foshay specific antiserum has been disappointing, and more recently a trial of several of the sulfonamide compounds resulted in no clinical improvement whatever. Penicillin was ineffective. All patients were given intravenous injections of the bismuth solution at the time of the first visit, which was usually on the third or fourth day after the patient was aware of being sick. Diagnosis must be made and treatment started without the aid of the laboratory. Usually the characteristic clinical onset and the history of exposure to probable infection will supply the necessary evidence. During the last two years Jackson has used a solution of bismuth sodium tartrate especially prepared for intravenous use. The dose is estimated on the basis of 1 cc. per hundred pounds of body weight, but in children a relatively large dose (1 cc. for 50 pounds) may be given. The average number of injections required for cure is seven. Contrary to prevalent views, the intravenously administered bismuth is quite free from serious untoward manifestations. No death has occurred in this series of 61 cases. There was prompt recovery in all cases treated by intravenous injections of a solution of bismuth sodium tartrate, suggesting that the use of this solution is a specific procedure in the treatment of tularemia.

Visual Symptoms Caused by Digitalis.—Carroll reports visual symptoms that occurred in 6 patients who were taking digitalis. In 3 patients general symptoms of digitalis intoxication caused the patients to return to the internist for advice, but the other 3 came directly to the ophthalmologist because of visual disturbances. None of these suspected digitalis as the cause and none gave a history of taking digitalis until they were specifically questioned regarding it. The visual symptoms consisted in colored vision—chiefly white, green, yellow or red—flashes of light, positive colored scotomas and other visual hallucinations. There was no change in the visual acuity or

fields of these patients. It is suggested in the literature that if the intoxication is sufficiently profound a temporary cortical type of blindness may result. This condition may occur in patients receiving what is considered a normal dosage of the drug and may be the only symptom present. Recovery takes place within two weeks after the digitalis is stopped.

Insect Problems in World War II, with Special References to Insecticide DDT. F. C. Bishopp.—p. 373.

Cure of Typhoid Carriers.—Feemster and Smith say that as various chemical and biologic agents have been tried and found to be failures it has been necessary to return repeatedly to cholecystectomy as the only method which regularly cures an appreciable number of carriers. The authors review observations on 68 typhoid carriers operated on in Massachusetts between 1924 and 1944. There have been 63 cures and 5 failures. Medical treatment, even with sulfonamide compounds, cannot be relied on to eliminate the gallbladder focus. The authors have had 4 failures with sulfaguanidine and succinylsulfathiazole. To establish that a person is a bile carrier and supposedly a gallbladder carrier, it is necessary to demonstrate typhoid bacilli in the bile by duodenal drainage prior to operation or by culture taken from the gallbladder at the time of operation. The criteria of cure should consist of a careful bacteriologic follow-up for not less than twelve months of negative stool cultures and at least one negative bile. Cholecystectomy is still the only effective method of curing typhoid carriers.

Morbid Anatomy of Typhus.—In April 1944 epidemic typhus broke out in a hospital for patients with mental disease in Guatemala City. Numerous blocks of necropsy tissue were forwarded to the Army Medical Museum in Washington, D. C., and examined by Golden. The lesions of louse borne epidemic typhus as seen in 10 fatal cases in this outbreak may be classified in two groups. One group consists of the specific vascular lesions of rickettsial infection. The vascular lesions appeared to be most pronounced in the central nervous system and the testes, and they were responsible apparently for a certain degree of destruction or inflammation of the regional tissues. The other group of lesions included interstitial myocarditis, meningitis, focal cellular necrosis of the adrenal glands, interstitial nephritis, hemoglobinuric nephrosis and focal necroses of the liver and spleen. The spinal cord showed lesions identical with those of the cerebral hemispheres, the cerebellum and the brain stem. The lesions of the pons and the medulla were the most severe. The state of collapse may be correlated with focal necrosis and cytolysis of the adrenal glands, although one must also consider interstitial myocarditis and the lesions of the central nervous system in the pathogenesis of that state. Hemoglobinuric nephrosis is of significance because similar lesions are seen in severe burns, massive crushing of muscles and certain shocklike states. Apparently, epidemic typhus may be added to the list of diseases in which interstitial nephritis may be encountered.

Coronary Arteriosclerosis and Myocardial Infarction.—Holyoke shows that the injection and dissection technic of Schlesinger has made possible a more accurate concept of the significance of sclerosis of the coronary arteries in relation to myocardial disease. He studied an unselected series of 70 adult hearts at the necropsy service of the Mary Hitchcock Memorial Hospital, Hanover, N. H., by means of the Schlesinger technic. After injection of the vessels and x-ray examination of the heart the coronary arteries were dissected, and all occlusions and narrowings were recorded as to location and length of the portion of vessel involved. In narrowing without occlusion, the degree of constriction was estimated. Occlusions of the coronary arteries were demonstrated in 12 of the 70 hearts. In these 12 hearts thirty-one points of obstruction were demonstrated. Thirteen were in the main stems of the three principal coronary arteries. Eighteen were in the large branches. Inter-

arterial anastomoses were demonstrated in all hearts with pronounced arteriosclerotic narrowing. Only in the presence of hypertrophy were such anastomoses demonstrated in other hearts. In 3 of 11 hearts with old occlusions of the coronary arteries there were no old infarcts. In 2 of 5 hearts with recent occlusions of the coronary arteries there were no corresponding recent infarcts. In 1 of 4 hearts with recent infarcts there was no recent occlusion. Grossly recognizable scars were present in the myocardium of 26 of the 70 hearts. Data from this work and from the literature emphasize that coronary arteriosclerosis is only one of the many factors which may be responsible for the anatomic changes and the symptoms resulting from myocardial anoxia.

Benzol Poisoning—Delayed: Case Report. Adelaide R. Smith.—p. 118.

Intervertebral Disk Injury.—Marble and Bishop attempt to present impartially some of the facts relating to intervertebral disk injury from the standpoint of an industrial surgical clinic. The sources of the material are the records of one of the largest insurance companies in the United States interested in workmen's compensation. The facts as gathered represent a cross section of the work of both neurosurgeons and orthopedic surgeons throughout the country. Compensable cases represent probably the most important group, since back injury in industry is frequent and the results of therapy vital to the future of the patient. Of 496 industrial patients suspected of having sustained herniation of the intervertebral disk 92, or approximately one fifth, were operated on, while four fifths received other therapy. The 92 cases are analyzed from the standpoint of cost, disability, cause and diagnostic criteria Less than 50 per cent of cases show a favorable result.

Primary Degeneration of Corpus Callosum.—Marchiafava and Bignami were the first to observe central necrosis of the corpus callosum in elderly Italian alcoholic addicts. Since their report in 1903 about 50 cases of the disease have been reported. Until recently most cases have been reported in native Italians. The first native American reported to have the disease had become addicted to crude Italian wine. Merritt and Weisman report 2 additional cases of Marchiafava-Bignami's disease. Both occurred in middle aged Italians, in at least one of whom a history of excess alcoholism could be established. Both patients had subsisted on grossly inadequate diets. The pathologic findings were limited to necrosis of the middle lamina of the corpus callosum in the first patient, but the second patient had extensive symmetrical lesions in the subcortical white matter of the hemispheres and middle cerebellar peduncles as well. The authors think that the clinical picture cannot be explained by the callosal lesion but requires postulation of a more diffuse cerebral disorder. They consider Marchiafava-Bignami's disease to be a form of chronic alcoholic encephalopathy for which an inadequate diet and prolonged alcoholism are necessary antecedents.

Lesions of Cervical Intervertebral Disk.—From a review of the literature Browder and Watson collected only 69 verified cases with protrusion or herniation of a part of the cervical disk. In this paper they present their experiences with 22 cases in which this lesion had disturbed the function of the cervical spinal cord and/or nerve roots. Twenty-one were verified at operation and 1 at necropsy. Three different types of pathologic processes were encountered: (*a*) discrete, oval or rounded nodules projecting into the ventral vertebral canal, (*b*) true dorsal herniations of the nucleus pulposus and (*c*) ridges of annulus fibrosus surmounting hypertrophic bone at the margins of the adjacent vertebra. A negative Queckenstedt test does not exclude the presence of such a lesion. The operative mortality for the series was zero. One patient died before coming to operation.

Foreign Bodies in Gallbladder.—A woman aged 61, whose chief complaint was pain in the left hypochondrium, loss of appetite and a loss of 25 to 30 pounds (about 12 Kg.) in the past year, had an acute episode of pain in the right subcostal area one year ago. A physician told her that she probably suffered from a chronic gallbladder disease and probably gallstones. She made an uneventful recovery from this acute episode. Since that time there has been some tenderness and soreness in the right upper quadrant of the abdomen. She has been intolerant to fatty foods and has had increasing episodes of epigastric distress and pain. The x-ray examination revealed two metallic bodies in the gallbladder. At operation the liver was found to be normal except that there were dense fibroid adhesions anchoring the gallbladder firmly in its bed, apparently where the metal pins had perforated the gallbladder into the liver bed. The patient recovered. She stated that approximately twenty years ago she swallowed a closed safety pin. She has been a dressmaker for the past thirty years and commonly held many pins in her mouth while fitting clothes. Heatley and Bascom discuss whether the pins found in the gallbladder were the shafts of a safety pin, the spring and clasp ends having become oxidized, or whether they were straight pins swallowed on different occasions.

Treatment of Schistosomiasis.—Hernández Morales says that in recent years physicians in Puerto Rico have become conscious of the frequent occurrence of schistosomiasis. A large number of patients with schistosomiasis were observed at the University Clinic of San Juan, and for the present study 157 of these cases have been selected. Trivalent antimony compounds are the most effective of all drugs in combating schistosomiasis. Antimony and potassium tartrate, antimony and sodium tartrate and fuadin appear to be the drugs of choice; anthiomaline deserves a more extensive trial. It seems that in spite of the fact that fuadin is effective in only 50 to 60 per cent of the cases its low toxicity and the ease with which it can be administered should make it the drug of choice. It is marketed in the form of a clear isotonic solution with 6.3 per cent of the drug; hence 1 cc. represents 8.5 mg. of trivalent antimony. Fuadin is administered intramuscularly with very little discomfort. For an adult the first three injections, of 1.5, 3.5 and 5 cc. respectively, are usually given daily. Subsequent doses of 5 cc. are given every other day or every three days until a total of 45 cc. has been given. Treatment can be repeated after a rest period of one to two weeks. Although this amount of drug may not be adequate for cure in a certain percentage of cases, the author does not favor the excessive amounts recommended by Cawston, who gives total doses of 60 cc., or by Valencia Parparcen, who gives up to from 100 to 150 cc. The high doses are likely to cause severe toxic reactions. The author presents case histories representative of toxic reactions. The more common reactions are nausea, vomiting, epigastric pain, pain in the joints and loss of weight. Of the more severe reactions peripheral neuritis is the most frequently found. A case of herpes zoster and of purpura hemorrhagica were recently observed. In 1 case the administration of fuadin apparently reactivated an old tuberculous process.

Loeffler's Syndrome with Response to Emetine.—A man aged 20, whose temperature varied between 99 and 100.4 F., presented clinically a condition resembling one of those transitory pulmonary infiltrations with eosinophilia first described in 1936 by Loeffler. Examination revealed increased vocal fremitus and vocal resonance in the upper third of the right lung and crepitations in the right apex and midzone. X-ray examination showed what was presumed to be characteristic tuberculous infiltration of both lung fields. A series of eight sputums were negative for tubercle bacilli, and no amebas nor fungi were found in the sputum or the stools. Daily intramuscular injections of emetine were given for ten days. The patient showed a rapid and dramatic response. His cough and sputum decreased rapidly, his appetite improved and he became symptom free. X-ray examination twenty-five days after the first one showed clear lung fields. Randall calls attention to the rapid resolution of the pulmonary lesions, the relationship this had to emetine treatment and the problem which remains of whether such cases really have an amebic origin when they occur in a district where amebiasis is endemic.

*Production of Penicillin on Media Made from Vegetable Extracts, Particularly Extracts of Pea. R. P. Cook and W. J. Tulloch.—p. 555.

Production of Penicillin.—Cook and Tulloch report experiments which had the purpose of finding a simple, cheap and easily made medium that might be substituted for the synthetic substrates and Coghill medium and to determine the most favorable conditions for cultivation in such a medium. A strain of Penicillium notatum was grown on a variety of "natural" mediums prepared by extracting various vegetable products and the yield of bacteriostatic substance was assessed. Of the vegetables tested, peas and pea flour gave the highest yields. The authors describe a method of obtaining moderate yields of penicillin by growth at 22 C. in watery extracts of pea. Maximum yield occurs about the eighth to the tenth day, after which the medium becomes alkaline. The product obtained is not "notatin" and is easily extracted with ethyl acetate from the medium acidified with phosphoric acid. When neutralized it is neither pyrogenic nor toxic in the doses tested (50 units for a mouse of 17 Gm. and 3,000 units for a rabbit of 2 Kg.).

Oxophenarsine Hydrochloride in Malaria.—Dao L. encountered a patient with a genital chancre and a strongly positive Kahn reaction, with fever of the tertian type and schizonts of Plasmodium vivax in the blood. The fever disappeared after the second injection of oxophenarsine hydrochloride (mapharsen) and splenomegaly after the fifth injection. Dao L. administered oxophenarsine hydrochloride to 16 patients with acute malaria, to 12 with relapsing malaria and to 18 with malarial splenomegaly. He obtained favorable results in acute attacks of tertian malaria. Caution is necessary in cases of plasmodium falciparum. In the relapsing cases of malaria the fever usually subsides after the second injection of the drug; also it causes reduction of small recent splenomegalies. In splenomegalic patients with acute febrile attacks the author first employs oxophenarsine hydrochloride alone and after the fever subsides he uses the combination of oxophenarsine hydrochloride and typhoid paratyphoid vaccine. This combination was effective also in a third of the patients with chronic splenomegaly.

Pregnancy Nephrosis.—Nonnenbruch reports 5 instances of pure lipoid nephrosis with nephrotic syndrome in women after childbirth. The clinical picture was that of hypoproteinemia, shifting to the left of the albuminous substances of the blood, lipemia, lipoiduria and tendency to edema. Rise of blood pressure and eclampsia preceded in 2 cases and recovery occurred in one of them. One case presented a pure nephrosis in the second month of pregnancy. The nephrosis persisted for two years after the interruption of the pregnancy and recovery took place after an intercurrent fever. The pregnancy kidney is to be considered as nephrosis associated with edema and rise of blood pressure and in many instances with hematuria, but pregnancy kidney is not to be considered as diffuse glomerulonephritis in which condition a transition into a pure nephrotic syndrome was never observed. The edema in the nephrotic syndrome may depend on psychic excitement and that applies to the increase in the edema as well as its disappearance. Renal changes on the one hand and rise of blood pressure and edema on the other may have the same origin in diffuse glomerulonephritis and may be considered as coordinated manifestations of this condition. A common cause for the renal and extrarenal processes may have to be considered likewise in pregnancy kidney. Rise of blood pressure and edema may be the extrarenal results of this condition, as well as those of

glomerulonephritis, but glomerulonephrosis with heavy loss of albumin and without any inflammatory reaction of the kidney may develop in the absence of "nephritis." There may be various transitional stages to pure lipoid nephrosis with the nephrotic syndrome. Pregnancy nephropathy requires cooperation of the gynecologist with the internist.

Origin of Pylorospasm.—Bonell studied the excretion of protective ferments in the urine of 19 normal male and female infants with mild disorders of nutrition of ages between 20 days and 13 months. Placenta, ovary, corpus luteum and testis were used as substrates for Abderhalden's reaction. The elaboration of specific protective ferments was studied in a second series of 10 male infants with pylorospasm between the ages of 3 and 7 weeks. The secretion of specific protective proteinases which split placenta proteins but frequently cause the disintegration of substrates from the ovary, corpus luteum and testis was demonstrated in the urine of all the infants up to 3 months of age and in 2 infants 4 months old. The excretion of these ferments, which were specific for the hormone substrates of the mother, could not be demonstrated in the urine of infants with pylorospasm. Their organism does not seem capable of producing protective ferments causing the breakdown of proteins which had been taken over by the infant from the mother and which were foreign to the blood or at least to the plasma of the infant. This is regarded as experimental proof of Stolte's concept of the origin of pylorospasm. The clinical picture of vomiting may therefore be included among the pregnancy reactions of the newborn. No other theory furnishes better explanation for the limitation of pylorospasm to a definite age and its predilection for one sex. The endocrine origin of pylorospasm is likewise suggested by clinical and roentgenologic observations which prove that pylorospasm requires a certain length of time for its full development. Further proof is to be seen in the high incidence of spontaneous recoveries after the third month, a period which coincides in the infant with the time at which the effect of the hormone of the mother gradually disappears.

*Therapy of Acute Leukemia and of Agranulocytosis. O. Scharff.—p. 169.

Therapy of Acute Leukemia.—Scharff reports good results with sulfathiazole therapy in 3 cases of severe necrosis of the oral mucosa and septic agranulocytosis in the presence of chronic lymphadenitis in 1, with acute myelosis in another and with agranulocytosis in the third. The first patient, a man aged 44, was given 6 Gm. of sulfathiazole the first day and 4 Gm. for the two following days. The acute septic leukemia with its immediate threat to the patient's life gave place to chronic lymphadenosis complicated by this septic condition. Death occurred from the primary chronic disease four months later. Recovery from acute myelosis developing in the second case from chronic myelosis and combined with a large tumor of the spleen was obtained with 8 Gm. of sulfathiazole on the first and second days and of 4 Gm. on the third day. The early stage of chronic myelosis was restored and the patient, a man aged 37, was dismissed free from complaints. The third patient, a man aged 33 with septic agranulocytosis, was cured by two courses of sulfathiazole treatment. The first consisted of 8 Gm. of sulfathiazole for three days and of 4 Gm. for one more day. The recurrence of the acute septic condition required a second course. The rapid disappearance of the severe necrosis of the oral mucosa in all 3 cases and of the prepuce and the tympanic membrane in the second case was striking. The cure of the septic condition is to be considered as the result of the sulfathiazole treatment, since acute leukemia or septic agranulocytosis does not subside spontaneously. The same good results obtained in these 3 different cases suggest a relationship between the three pathologic conditions.

Simultaneous Treatment of Syphilis with Specific Drugs and Fever.—Haxthausen administered to 21 patients with primary syphilitic lesions 0.3 Gm. of neoarsphenamine, and to 20 patients 0.3 Gm. of neoarsphenamine and fever produced by simultaneous intravenous injections of a Bacillus aerogenes faecalis vaccine in doses of 80 to 100 million bacilli. In the first group of patients the spirochetes disappeared in 4 of the 21 patients within twenty-four hours, whereas the same result was obtained in 17 of the 20 patients in the second group. Fever vaccine therapy alone did not have much effect on the number and the motility of the spirochetes three days after the fever. The effect of bismuth on the presence of spirochetes in syphilitic papules demonstrated a similar accentuation of the bismuth effect by fever therapy. This suggested that intensification of the effect of the specific drugs may result from combining fever with specific drugs. It is advisable to employ fever therapy simultaneously with the specific drugs in old refractory cases, and particularly in cases in which the usual treatment is ineffective from the onset or in which treatment is soon followed by a relapse. One should employ doses of 0.6 Gm. for women and 0.75 Gm. for men. No untoward reactions were observed from these doses and fever therapy, whereas in 1 refractory case in which neoarsphenamine was given in 0.9 Gm. doses the second combined injection was followed by the occurrence of hepatitis.

Acta Medica Scandinavica, Stockholm

Anaphylactic In Vitro Reaction to Tuberculin. A. Grönwall.—p. 470.
Cardiovascular Observations in Myasthenia Gravis and Dystrophia Myotonica. E. Ask-Upmark.—p. 502.
Atropine Treatment of Sequel of Epidemic Encephalitis. I. Vartiainen.—p. 536.
Determination of Erythrocyte Content of Circulating Blood by Labeling with Radium Phosphorus. G. Hevesy, K. H. Köster, G. Sørensen, E. Warburg and K. Zerahn.—p. 561.

Epinephrine Preparation with Retarded Action.—Kallós and Kallós-Deffner used a slow acting epinephrine preparation (adrenaline retard) in experimentally induced asthma in guinea pigs. The preparation is effective in the prophylaxis of asthma. Experimentally produced attacks of asthma which without treatment would probably have a fatal outcome can be arrested by the intramuscular injection of the slow acting epinephrine preparation. The effect seems to persist for several hours. The preparation is well tolerated and has no damaging effect on the tissues.

Book Notices

The Precentral Motor Cortex. Edited by Paul C. Bucy. Illinois Monographs in the Medical Sciences, Vol. IV, Nos. 1-4. Paper. Price, $4.50. Pp. 605, with 140 illustrations. Published Under the Auspices of the Graduate School. Urbana: University of Illinois Press, 1944.

This is a timely monograph designed to bring to date the rapidly accumulating knowledge of the motor cortex. The editor, Dr. Paul C. Bucy, has selected his contributors wisely and chosen the subject material critically. The result is a volume of splendid contributions concerning all aspects of the problem of the motor cortex. It is quite fitting that this volume should be contributed by American authors, for it is in this country that much of the recent investigation of the motor cortex has unfolded, though the impetus for such investigation may have come from Dr. Otfrid Foerster, to whom the volume is dedicated.

The scope of the work is seen in the contents: (1) architecture of the precentral motor cortex, G. von Bonin; (2) role of architectonics in deciphering the electrical activity of the cortex, James L. O'Leary; (3) afferent connections, A. Earl Walker; (4) efferent fibers, Paul M. Levin; (5) pyramidal tract, Sara S. Tower; (6) excitatory and inhibitory processes within the motor centers of the brain, N. Bubnoff and R. Heidenhain; (7) corticocortical connections, W. S. McCulloch; (8) somatic functions, Margaret A. Kennard; (9) relationship to the cerebellum, Percival Bailey; (10) autonomic functions, Margaret A. Kennard; (11) frontal eye fields, Wilbur K. Smith; (12) electrical excitability in man, Theodore C. Erickson; (13) effects of extirpation in man, Paul C. Bucy; (14) relationship to abnormal involuntary movements, Paul C. Bucy; (15) clinical symptomatology, Charles D. Aring; (16) pathology, Charles Davison; (17) significance of the precentral motor cortex, Marion Hines.

Some conception of the strides which have been made in the understanding of our knowledge of the precentral cortex in recent years may be recognized by the disclosure of the significance of the strip area, by the working out of cortical and subcortical connections, by the elucidation of the meaning of flaccidity and spasticity, in which much still remains to be done, by the determination of the origin of the pyramidal tract, by the mapping out of extrapyramidal or parapyramidal cortical areas and connections and by the results of extirpation in man. These are but a few of the problems to which new data have been contributed, and it is safe to assert that much new material remains to be disclosed.

The editor and the authors are to be congratulated not only on a fine volume but on the part which American neurology, neurosurgery and neurophysiology have played in the amplification of our knowledge of the motor cortex.

A complete bibliography adds to the value of the volume. It is recommended without reservation to all those interested in neurology, whether their field is clinical or laboratory.

Emotional Problems of Living: Avoiding the Neurotic Pattern. By O. Spurgeon English, M.D., Professor of Psychiatry, and Gerald H. J. Pearson, M.D., Associate Professor of Child Psychiatry, Temple University Medical School, Philadelphia. Cloth. Price, $5. Pp. 438. New York: W. W. Norton & Company, Inc., 1945.

The first half of this book is devoted to a thoroughgoing discussion of the emotional disturbances that arise in infancy and childhood. Growth is conceived as a series of periods classified as oral, anal, phallic and latent, proceeding then to puberty and adolescence, work and marriage. Psychologic disturbances later in life seem to result largely from the frustrations of pleasure that result in hostility, pain and hatred. Nail biting is considered a sign of poor emotional adjustment. The severe cases are part of the desire of the child to annoy and humiliate the parents. Most of the points made are illustrated by case reports. The volume is planned not only for the medical reader but also for medical students, teachers, nurses and social workers. The book is definitely orientated to psychoanalytic thinking. Many statements are made as conclusive which might still be considered in the realm of investigation. However, a careful reading of the work will aid greatly the understanding of the relation of mind to body and thus advance greatly the quality of medical practice.

The Chemistry and Technology of Food and Food Products. Prepared by a Group of Specialists under the Editorship of Morris B. Jacobs, Ph.D., Senior Chemist, Department of Health, City of New York. Volume II. Cloth. Price, $10.50; $19 per set of two volumes. Pp. 890, with 166 illustrations. New York: Interscience Publishers, Inc., 1944.

This volume contains the four concluding sections of this treatise on food and food processing and is concerned entirely with the technology of processing. Such matters as conveying of foods in various forms and their storage are considered. Discussion is given to the principles of methods used in preparing food for storage. In later sections the more detailed technical procedures and problems of preservation are taken up. Standards of quality which must be met to pass federal, state and municipal requirements are outlined and references given to detailed description of federal standards adopted up to February 1943. Much information is given on the measures used to maintain sanitary control. The important and informative last section describes the production of all substantial types of processed and natural foods, with inclusion of many pictures. Facts and figures on the methods of preparation of alcoholic beverages and their chemical composition are found here. The treatment of water for various industrial uses as well as for drinking purposes is covered. This volume serves the valuable purpose of giving a broad survey of the field of food processing. The reader is oriented in each subject but would need to look further for detailed information. As an overall perspectus of the food industry the book would be hard to equal.

Science in Progress. By Walter R. Miles, and others. Edited by George A. Baitsell. Foreword by Lorande Loss Woodruff. Fourth series. The Society of the Sigma Xi, National Lectureships 1943 and 1944. Cloth. Price, $3. Pp. 331, with 106 illustrations. New Haven, Conn.: Yale University Press; London: Oxford University Press, 1945.

This volume is the fourth of a series which makes available Sigma Xi lectures dealing with fields in which there has been great progress. The scientist will find these lectures uniformly of high quality. The authors are the men who themselves have been in the forefront of research. The book is excellently printed, with numerous black and white and colored illustrations. The subjects especially involved in the present volume which would be of interest to physicians include psychologic aspects of military aviation, by Walter R. Miles; the physical structure and biologic action of nerve cells, by Detlev W. Bronk; energy and vision, by Selig Hecht; chemical transmission of nerve impulses, by Otto Loewi; present status of the vitamin B complex, by C. A. Elvehjem, and blood and blood derivatives, by Edwin J. Cohn.

The Svedberg 1884 $\frac{30}{8}$ 1944. [Anniversary Volume.] Boards. Pp. 731, with illustrations. Uppsala, Sweden: Almqvist & Wiksells Boktryckeri A.B., 1944.

This volume is a tribute by grateful associates, assistants and pupils to The Svedberg, professor of physical chemistry at the University of Uppsala, on his sixtieth birthday. Because of the war the contributions are practically all of Swedish origin. The English, German, Swedish and French languages are used in the order of frequency as mentioned. There are fifty-five papers by some seventy-five authors, dealing mainly with investigations in chemistry and its borderlands, particularly technology, but including also biology and medicine. The papers constitute an impressive record of Swedish chemical research during recent years and especially in the Institute of Physical Chemistry in Uppsala, where Svedberg has carried on his work since 1931. The publication of this handsome, well edited memorial volume was made possible by grants from Swedish industrial concerns.

Yeoman's Hospital. By Helen Ashton. Cloth. Price, $2.50. Pp. 271. New York: Viking Press, 1945.

The author studied medicine between 1920 and 1926 after serving as a nurse in the first world war. Most of her novels have a medical background. This novel tells the story of a nonprofit voluntary hospital in England, of a few days in the life of the institution when a new class of nurses begins, when the board of the hospital is concerned with its future, when the members of the resident staff are competing for an appointment in surgery. A young woman doctor who is a surgeon and a somewhat morose pathologist with a duodenal ulcer are the heroine and the hero of the book. A somewhat careless young surgeon who misses a diagnosis of brain abscess helps to make

the medical aspects interesting. Miss Ashton writes professionally and is exceedingly skilful in organizing her story. It serves, as does many another British novel, to picture certain aspects of medical practice more accurately than they appear in the writings of the economists and the politicians. She reveals the real concern of the medical profession over the disappearance of the voluntary hospital. She reveals the true opinion of the medical profession of the quality of panel practice, and she reveals also the scale of living of the British worker as it is seldom revealed in the writings of those who speak so learnedly about the Beveridge plan. The novel is well worth the time of any physician who likes to read fiction with a medical aspect.

Nursing: A Profession for College Women. Paper. Price, 25 cents. Pp. 35. Published by the Nursing Information Bureau of the American Nurses' Association co-operating with the National League of Nursing Education and the National Organization for Public Health Nursing. New York, 1945.

This handbook, prepared by leading organizations in the field of nursing education and service, contains a wealth of information for young women who are interested in professional nursing and wish to contribute to the care and welfare of the sick. It describes educational requirements, types of nursing schools, cost of preparation, available financial aid, placement opportunities, positions in military and civilian service, working conditions, salary ranges, opportunities for professional and personal development and many other significant factors. Selected references are included as well as other sources from which specific information can be obtained. While this pamphlet may find its greatest use among counselors in colleges and high schools, it will be equally valuable as a direct aid to individual students interested in nursing education. Since there is still an urgent demand for additional nursing personnel in relation to military and civilian needs, it is hoped that the information contained in this handbook will be given wide distribution throughout the country.

Annual Review of Physiology. James Murray Luck, Editor. Victor E. Hall, Associate Editor. Volume VII. Cloth. Price, $5. Pp. 774. Published by the American Physiological Society and Annual Reviews, Inc. Stanford University P. O., California: Annual Reviews, Inc., 1945.

This book contains important and fundamental contributions to physiology. In spite of the war it is the largest volume of the series yet published. It contains a wealth of valuable information, including chapters on the peripheral circulation, respiration, digestive system, blood, heart, special senses, exercise and other important subjects by thoroughly qualified investigators. As in previous years, this is an invaluable book of source material for investigators working in physiology or in the borderland between clinical medicine and physiology.

An Introduction to Animal Biology. By John B. Parker, Ph.D., and John J. Clarke, Ph.D. Second edition. Cloth. Price, $3.75. Pp. 532, with 172 illustrations. St. Louis: C. V. Mosby Company, 1945.

The second edition follows the general plan of the first edition, but the material has been brought up to date and expanded. The book is intended for a one semester college course. The authors have developed the material in such a way that the student sees the subject as a whole, rather than losing himself in a maze of details. Animal forms which are of economic or medical importance are emphasized. The subjects of heredity, genetics and evolution, as well as hormones and vitamins, are treated in separate chapters. An appendix groups the material together in tabular form, and the glossary covers fourteen pages.

Social Work Year Book 1945: A Description of Organized Activities in Social Work and in Related Fields. Russell H. Kurtz, editor. Eighth issue. Cloth. Price, $3.25. Pp. 620. New York: Russell Sage Foundation, 1945.

This is the eighth of the series which has made a place for itself as one of the most reliable reference works for those in the field of public health, medicine and social work generally. The book is a dependable guide to the agencies in the field and the advances that have been made in specific areas of social work. Of special interest in the current number are sections devoted to the veterans, social insurance, foreign relief and rehabilitation, and interracial and intercultural activities. Excellent bibliographies accompany each of the discussions.

Science Today and Tomorrow. By Waldemar Kaempffert. Second Series. Cloth. Price, $2.75. Pp. 279. New York: Viking Press; Toronto: Macmillan Company of Canada, Ltd., 1945.

Mr. Waldemar Kaempffert has collected here the essays which he has contributed at various times to various publications. Of special interest to physicians in this volume is a chapter called "Sick Medicine Needs a Doctor." It is replete with the misrepresentations which are expected when Mr. Kaempffert writes about medicine, of which he knows little and concerning which he seems unwilling to learn more. He charges, for instance, that physicians must practice by the fiat of their national organization. Actually the national organization adopts principles of ethics which members follow because they believe in them. For one who presumes to be educated in the scientific method Mr. Kaempffert writes with innumerable and extraordinary prejudices. Indeed, his choice of words is designed particularly to create prejudice. Mr. Kaempffert does not believe that doctors charge according to the patient's ability to pay. He thinks they charge all the traffic will bear. He charges that voluntary insurance does nothing for preventive medicine but disregards the fact that there is little or no preventive medicine in any compulsory sickness insurance plan. If the rest of Mr. Kaempffert's book is as bad as this chapter, investment will represent a considerable waste of money. Fortunately, however, the reader has free choice—he can take it or leave it. It is our recommendation that he leave it.

Vitamins and Hormones: Advances in Research and Applications. Edited by Robert S. Harris, Associate Professor of Nutritional Biochemistry, Massachusetts Institute of Technology, Cambridge, and Kenneth V. Thimann, Associate Professor of Plant Physiology, Harvard University, Cambridge. Volume II. Cloth. Price, $6.80. Pp. 514, with illustrations. New York: Academic Press, Inc., 1944.

This volume contains material on aspects of vitamins and hormones not dwelt on in volume I. The subjects considered include the role of vitamins in the anabolism of fats; the chemistry of biotin; the nutritional requirements of primates other than man; physiologic action of vitamin E and its homologues; the chemistry and physiology of vitamin A; para-aminobenzoic acid—experimental and clinical studies; critique of etiology of dental caries; vitamin and cancer; effect of androgens and estrogens on birds; hormones and cancer; x-ray crystallography, and sterol structure. There appears to be little rhyme or reason to the selection of topics. These volumes cannot serve as a reference source on the title subjects of vitamins and hormones because of the scattered coverage given thus far. The editors may feel that information is assembled here which is not found in other textbooks. This is actually true and is probably the objective of the work. This publication can be recommended as a particularly good and complete source of factual information on the subjects presented. Each contributor is a recognized expert who surveys the field with facts from the literature and but little discussion. Extensive reference lists increase the value of the books to the reader.

Clinical Roentgenology of the Digestive Tract. By Maurice Feldman, M.D., Assistant Professor of Gastroenterology, University of Maryland, Baltimore. Second edition. Cloth. Price, $7. Pp. 769, with 551 illustrations. Baltimore: Williams & Wilkins Company, 1945.

The second edition of this complete study of the gastrointestinal tract from the roentgenologic point of view has been thoroughly revised and newly illustrated. Every condition of the entire gastrointestinal tract has been covered; the more commonly seen pathologic entities have been thoroughly studied and the rarer conditions described in brief. A complete bibliography at the close of each chapter allows the reader to follow up whatever subject he may be particularly interested in. No pathologic condition in any way associated with any part of the gastrointestinal tract has been omitted. The subject matter is handled clearly and concisely, and all of the more recently described developments in x-ray examination have been added. Numerous x-ray reproductions and artist's drawings illustrate each condition. In this way the volume can be considered as an atlas for study by the medical student. It is designed not only for the roentgenologist but also for the gastroenterologist —the general practitioner and the medical student. The need for such a volume is evidenced by the difficulty usually encountered in seeking information on the many aspects of this large subject.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

RINGWORM OF THE SCALP

To the Editor:—What is the latest and most successful treatment for tinea capitis?

M.D., Pennsylvania.

ANSWER.—In the present rather widespread epidemic of tinea capitis the offending organism in most cases is Microsporum audouini. Infections caused by this organism are extremely resistant to treatment. The average case may last for eight or nine months. The most rapid and successful method of treatment is epilation of the diseased hair by means of the x-rays. This, however, is a most delicate operation and should be done only by some person experienced in this type of treatment. The machine should be accurately standardized and the quantity of x-rays necessary to produce a temporary alopecia definitely known; for further details of this treatment one should consult George M. MacKee's X-Ray and Radium Treatment of Diseases of the Skin (ed. 3, Philadelphia, Lea & Febiger, 1938, chapter 28).

Treatment with topical applications is slow, but if the hair is clipped short an ointment containing 10 per cent iodine crystals in aquaphor can be used twice daily. This should be applied with a soft toothbrush morning and night, and as soon as a reaction occurs and the scalp becomes tender, treatment should be suspended for a few days and then resumed.

Another ointment of value is composed of precipitated sulfur 6 Gm., salicylic acid 3 Gm., castor oil 6 cc. and petrolatum to make 60 Gm. Still another is ammoniated mercury 3 Gm., salicylic acid 2 Gm., petrolatum 30 Gm. and hydrous wool fat to make 60 Gm.

COMPLICATIONS AFTER CISTERNAL INJECTION OF RADIOPAQUE OIL

To the Editor:—One year ago a patient aged 35 had lipiodol 2.5 cc. injected cisternally to prove a diagnosis of a ruptured cervical disk. Following the injection the patient had a severe headache and a temperature of 102 F. for twenty-four hours. This was followed by severe pains in both hips and in the lower part of the back which necessitated sleeping in Fowler's position for ten days. For the next week the pains in both hips were less severe but were accentuated by walking or standing and were accompanied by pain in the sacrum on coughing, sneezing or laughing heartily. At the end of three weeks these pains had disappeared except for slight pains in both hips. About a month later the pain came back in both hips more severely than ever, particularly in the right hip. The pain was alleviated by bed rest and was accentuated by walking or standing. These attacks of pain in the right hip and back continued off and on for the next six months. At this time an attempt was made to remove the lipiodol, and half of it was removed. Following the removal of part of the lipiodol the pain subsided but two months later returned in the right hip, not as severe as originally but more chronic and persistent. An x-ray film of the lumbosacral area taken one year after the injection of the lipiodol showed lipiodol to be scattered on most of the nerve roots from the first thoracic down to the end of the spinal cord, with the bulk of the lipiodol in the sacral sac and immovable. The x-ray film showed also considerable calcification of the pelvic arteries. Is lipiodol in the subarachnoid space productive of irritation of the nerve root? If so; how long does such irritation last, and what is the prognosis? What references in the literature are there on the effects of lipiodol used in the spinal canal?

Harry L. Strachan, Captain, M. C., A. U. S.

ANSWER.—Current opinion, based on extensive experience, is that radiopaque iodized oil is of little value in the diagnosis of most ruptured intervertebral disks with compression of one of the cervical roots; in the future lipiodol or similar substances will probably be used only in those cases in which a herniation of an intervertebral disk has been confused with a spinal cord tumor.

The acute symptoms of headache, fever and irritation of the lumbosacral nerve roots which occurred in this case, though considerably more severe and persistent than are usually seen, are not rare following the intraspinal injection of radiopaque oils. In the vast majority of such cases these symptoms subside within twenty-four hours and in the remaining few within the next three days. Only rarely does irritation of the spinal roots and of the meninges persist beyond that. The most persistent irritation resulting from iodized oil is usually seen in cases in which the original symptoms arose from inflammatory disease of the meninges and spinal nerve roots. In order to avoid such irritation it is now common practice to remove the oil immediately after fluoroscopy whenever that is possible. Either lipiodol or pantopaque can be removed by aspiration through a large (18 gage) lumbar puncture needle by having the patient on his abdomen on the tilting fluoroscopic table and puddling the oil about the end of the needle.

Cases in which irritation of the spinal roots, definitely established as due to iodized oil, has persisted for longer than a few weeks are so rare that few if any have been studied. It is thus impossible to state whether, in the case cited, the symptoms result from lipiodol, as seems possible, or are secondary to the disease process for which the myelographic examination was originally made. It is likewise impossible to guess, with anything like worthwhile accuracy, how long such symptoms might persist or what the ultimate outcome may be.

PAIN CAUSED BY MORPHINE AND CODEINE

To the Editor:—Following removal of the gallbladder, morphine and codeine have caused severe pain in the region of the common duct. Is Demerol effective in such a condition?

H. B. Aitkens, M.D., Le Center, Minn.

ANSWER.—Both morphine and codeine have been found to increase the tonus and motility of the common bile duct and of the sphincter of Oddi. Opium and derivatives of opium also increase the tonus and motility of the small intestine and colon and may produce violent spasms of localized areas of the intestine. Severe abdominal pain produced by morphine and codeine after removal of the gallbladder could be due to specific contraction of segments of the colon, small intestine or possibly also of the sphincter of Oddi. Isonipecaine ("Demerol") has been found to be effective as a substitute for morphine in relieving many types of pain and, in addition, seems to exert a definite spasmolytic effect.

ELECTRIC SHOCK TREATMENT FOR MENOPAUSAL SYMPTOMS

To the Editor:—A letter now being distributed stresses electric sleep therapy for nervous or mental disturbances occurring during the menopause. I am not aware that this treatment is a recognized one for this type of trouble. Please advise me as to its value and use.

Elvin L. Clark, M.D., Shelbyville, Ill.

ANSWER.—The letter in question was from the State of Illinois Division for Cooperative Extension Work in Agriculture and Home Economics in Shelbyville. It was a condensed reprint of an article by Dr. Foster Kennedy, published in the *Woman's Home Companion* for November 1944. In this article appears the following statement relative to treatment for the symptoms of the menopause: "The most remarkable of these new weapons is electric sleep therapy—a treatment as painless and simple as it is safe and successful. Between 80 and 150 volts of electric current are passed through the brain for one tenth of a second, and that is all there is to it." This treatment is electric shock treatment. Because of the possibility of harm, it should never be carried out except by responsible physicians. In the original article the statement is made that patients may receive such treatment in the morning and attend a matinée the same afternoon. Since lapses of memory sometimes occur following treatment, however, this advice is questionable. Moreover, there are other methods of treatment in the menopause besides shock therapy, and it would seem to be desirable, at least in the present stage of experimentation, to limit this form of treatment to patients under good control in hospitals. Bennett and Wilbur (*Am. J. M. Sc.* **208**:170 [Aug.] 1944) report a series of 75 cases of involutional melancholia or similar symptoms in the menopause, in 90 per cent of which good results were obtained with a combination of shock therapy and psychotherapy. All of these patients, it is said, were treated with estrogens without good results; 64 of the 75 had shock therapy. Many had to be given psychotherapy in addition. Ninety per cent were helped or apparently cured in the course of from four to six weeks.

NUMBNESS OF FINGERS IN METAL WORKERS

To the Editor:—A number of the employees of an aircraft plant complain of "numb" fingers. The only metal used is aluminum. The numbness has sudden onset and usually does not follow any anatomic distribution but involves half a finger, part of a finger or several fingers. There are no associated complaints.

Frank Meola, M.D., Akron, Ohio.

ANSWER.—Aluminum is a nontoxic metal and, as such, is not the cause of the condition described. However, "numb fingers" may arise from the handling of any sheet metal or other sizable object with comparatively thin edges. The numbness results from pressure on nerve endings or nerve filaments. An analogous state may appear if a pail of water is carried by a thin wire bale. Another condition among sheet metal workers and in other occupations is termed "dead fingers" or "white fingers." This occurs only during cold weather and after exposure to cold along with the use of vibrating tools either pneumatic or electric. This condition, which is partially or totally an angiospasm, may be limited to one hand and characteristically to certain fingers, depending on the type of tool and the method of its application to work. For greater detail as to pathology, treatment and prevention, reference is made to the International Labor Office "Encyclopedia of Occupations and Health," under "Pneumatic Tools." In addition to a lengthy original publication, further discussion may be found in the supplement to this encyclopedia.

PRESBYOPIA OR CHEMICAL INJURY OF EYES

To the Editor:—A compensation case involves a man who was working with a chemical called phenathiazene and who developed contact dermatitis of the hands and also around the eyes. This condition cleared up under treatment without any complications, but the man is now claiming that his glasses, which previously were used for reading only, are no longer satisfactory; he believes that exposure to this chemical has had some detrimental effect on his near vision. There was no involvement whatever of the cornea or conjunctiva, and I feel that the change in his vision is due to presbyopia, which has become more pronounced now at his age of 49, thereby necessitating that he wear glasses constantly. Could there be any connection between the exposure to this phenathiazene and his apparent sudden loss of accommodation?

M.D., Minnesota.

ANSWER.—The cornea and conjunctiva having escaped involvement in the contact dermatitis process, it is obviously necessary to search elsewhere for the causative factor in this patient's loss of accommodation. The most frequent and the most likely factor is the patient's age. From 45 to 50 years of age there is such a rapid development of presbyopia that the useful life of a pair of spectacles seldom extends beyond eighteen to twenty-four months.

POSTOPERATIVE IRRADIATION AND STERILIZATION FOR MAMMARY CANCER

To the Editor:—An unmarried woman aged 31 discovered a lump in her breast which on removal a few days later was pronounced malignant by two very reliable pathologists. A radical mastectomy was performed a week later. The glands were not found to be involved. A radiologist suggests that she receive x-rays to the chest and also that she be sterilized by x-rays or radium. Is this advisable?

Mark S. Shaine, M.D., New York.

ANSWER.—The question of postoperative irradiation for mammary cancer is not settled. Most radiologists advocate this procedure routinely, whereas some consider that it should be used only on special indications [see editorial "The Dilemma of Prophylactic Postoperative Irradiation in Mammary Cancer," *Radiology* **30**:769 (June) 1938]. The question of ovarian sterilization as a prophylactic measure against recurrence and metastasis is also controversial. Many students of the subject would consider the evidence inadequate to perform sterilization of the patient under consideration and would advise against the procedure in a patient 31 years of age without clinical evidence of recurrence or metastasis.

MANIFEST SILICOSIS AND DURATION OF EXPOSURE

To the Editor:—I have a patient who the radiologist says has pneumonoconiosis. There is a question of compensation insurance. How long does silicosis take to develop? The patient has been exposed to sand blast, steel dust and spray paint. What is the minimum time in which silicosis and siderosis can develop?

William Heard, M.D., Pentwater, Mich.

ANSWER.—Sandblasters working continuously in enclosed spaces without adequate ventilation sometimes develop silicosis in about two years. If the exposure has been unusually severe the x-ray examination may not reveal the characteristic nodular pattern, but there may be a diffuse obliterative shadow like that of pneumonia. Siderosis from the steel dust might be manifested as a simple exaggeration of the normal branching shadows of the blood vessels. As the picture of spray paint may also be diffuse, with or without fine nodulation, it would be hard to evaluate the effects of the combined exposures without more detailed information as to the lengths of exposure to the various irritants mentioned. As a general rule one expects heavy exposures to dust in excess of two years to produce demonstrable effects on the lungs.

CASTRATION FOR CARCINOMA OF MALE BREAST

To the Editor:—Two years ago a man aged 36 had a lump in the right breast. A frozen section showed a typical adenocarcinoma, and a radical breast amputation was performed at the time. He made an excellent recovery. The sections showed some metastases in the axillary glands. A course of 2,000 roentgens of radiation was given following the operation. The patient has remained clear of any evidence of local recurrence or distant metastasis until recently. He now has x-ray evidence of metastatic bone destruction in a rib, a vertebral body and in the ilium, with pain associated with the involved areas. Further radiation therapy can be given, but the possibility of hormone treatment comes to mind. There is a fair amount in the literature concerning the use of female sex hormone for carcinoma of the prostate, of ovariectomy for carcinoma of the female breast, and of male sex hormone for carcinoma of the female breast. I am not able to find any comparable information on treatment of carcinoma of the breast in the male. The following possibilities are suggested: the use of the female sex hormone (theelin, stilbestrol, and so forth); the use of the male sex hormone; castration. Which, if any, could be recommended in this particular case (this patient is a perfectly normal virile male)? If a hormone is considered most suitable, please recommend size of dose, method of administration and frequency. Would the advice given be on theoretical grounds or based on concrete experience with a comparable case? Any other suggestions available would be appreciated.

M.D., California.

ANSWER.—Castration has been performed for carcinoma of the male breast, and in some instances this procedure has caused regression and repair of metastatic lesions in bone and lungs. Cessation of pain is sometimes dramatic. The clinical results are somewhat similar to those noted following castration for carcinoma of the prostate.

CILIARY ACTIVITY IN NASAL SINUSES

To the Editor:—I am desirous of ascertaining the ciliary activity within the antrum. Where can I find a detailed description of an acceptable method, previously employed, for the determination of this information? What type of carbon particles have been employed?

W. W. Wilkerson Jr., M.D., Nashville, Tenn.

ANSWER.—Arthur W. Proetz has written a textbook which discusses the question raised in considerable detail (Essays on the Applied Physiology of the Nose, Annals Publishing Company, St. Louis, 1941). He furnishes in addition numerous references to other work done in this field.

INFANT FEEDING

To the Editor:—Can an infant between the ages of 2 and 6 months gain weight and develop normally on a formula of equal parts of condensed milk and water, omitting the carbohydrates but giving the usual supplements of cereals, vegetable and fruit?

Sidney Schwartz, M.D., Ripon, Calif.

ANSWER.—Yes, if cereals are started early enough, followed by the fourth month with vegetables or fruits other than orange juice or ascorbic acid, which in practice are usually started by the third or fourth week of life.

EXTERNAL POPLITEAL PALSY

To the Editor:—Following an operation for repair of cystocele, rectocele and relaxed urethral sphincter under general anesthesia, a paralysis of the left peroneal nerve (lateral popliteal) developed. The patient is a white woman aged 35. There is a complete left foot drop without evidence of returning function as yet—six days following operation. The patient was on the operating room table with the legs in the stirrups for one hour and ten minutes. The stirrups were each padded with a doubled face towel. Might this be a permanent injury? What is the recommended treatment and the prognosis?

Captain, M. C., A. U. S.

ANSWER.—The patient has an external popliteal palsy. Involvement of this nerve usually requires a long time for recovery, although it is not likely to be a permanent injury. The foot, the ankle and the leg should receive heat, massage and stimulation by the galvanic current three times weekly. The foot should be kept at right angles to the leg. In bed a sand bag is usually sufficient for this purpose; when not in bed the foot and leg should be in a cast or splint.

CAUSALGIC STATES IN PEACE AND WAR

GEZA DE TAKATS, M.D.
CHICAGO

There is an urgent need for the redefinition of causalgia. Burning pain associated with edema, glossy skin and a local rise in temperature is well known to follow certain partial injuries of the major nerve trunks. This group requires less attention because it is readily recognized and because its existence is not contested since the classic description of Weir Mitchell.[1] Far more important, however, is another large group in which the origin and level of sensory stimulation is not frankly obvious. Such patients are frequently misunderstood or discredited [2] but should be differentiated from patients suffering from purely psychogenic disorders, which occur after trauma following industrial accidents or war injuries.

It is well to look on the sensory pathways as being susceptible of stimulation at any level [3] (fig. 1). Our cases have been classified accordingly (table 1). Peripheral trauma activates the first, lowest neuron, producing vasomotor reflexes which under certain conditions are predominantly vasodilator.[4] The stimulation of posterior root fibers is known to produce painful vasodilator substances, which are diffusible and which readily produce glove or stocking type of cutaneous hyperalgesia, confusing an orthodox neurologic examination. Miller and I [5] showed that such a state is characterized by an increased blood flow as measured by a special plethysmograph. But for a clinical examination the rise in skin temperatures and the increased pulsations can differentiate such a limb from a hysterical one.

Such a first neuron lesion is encountered in any injury of the extremities in which peripheral nerves are contused, concussed or overstretched.[6] While the causalgias following injuries to the median and sciatic nerves are obvious, many other lesions have not been sufficiently emphasized. Attention should be called to lesions of the dorsal interosseous nerve in Colles' fracture, to a stretch of the peroneal or saphenous nerves in ankle sprains, to the irritation of the plantar nerve in painful lesions of the foot. Such lesions are not sufficient to produce anesthesia of the skin, and the hyperalgesia is purely subjective; however, a rise in cutaneous temperature and a cessation of sweating is often helpful in mapping out a sensory distribution before the hyperesthesia becomes diffuse.

If an injury causing continuous sensory stimulation is capable of producing such neurovascular phenomena, other conditions affecting the sensory pathways between the dorsal root ganglion and the peripheral receptors should also produce identical phenomena. In this material one of the glomus tumors, a glucose injection at the elbow producing irritation of the median nerve, a herpes zoster, an apical tumor of the lung infiltrating the intervertebral foramens or a paravertebral alcohol injection have demonstrated that they are capable of producing the causalgic state of burning vasodilatation, increased heat production, edema and osteoporosis (table 2).

Recognition of a lesion of the second neuron is not difficult when other localizing signs are present. That poliomyelitis is often very painful is sufficiently known; when the virus invades the internuncial neurons [7] the muscular hypertonus and the reflex hyperirritability of the poliomyelitic limb is readily understood. Such extremities, just like those in tabes, in combined degeneration of the cord or in an acute postscarlatinal myelitis, have shown burning pain, increased heat and edema (table 3).

While such lesions are of neurologic interest, their real significance lies elsewhere. The first neuron lesion, if unrecognized or mistreated, may ascend to this level and produce the same diffuse intractable dysesthesia, with mirror images to contralateral, symmetrical areas. Livingston [2] has postulated that the internuncial neurons become hyperirritable in the presence of persistent peripheral impulses. That the sensory barrage does produce chemical and electrical phenomena in the cord is documented by good evidence.[8] Such a cord is then comparable to that of the experimental animal whose cord has been touched with strychnine.[9]

Sensory phenomena after lesions of the highest third neuron are not unknown. Cortical trauma, the infarcted cortex with an intractably painful hemiplegia and certain cortical tumors do produce painful vasomotor

phenomena not unlike causalgia.[10] Again the fact must be kept in mind that, originating from lower sensory levels, the barrage of continuous impulses may so stamp their impression on the sensory cortex that it becomes the seat of projected, self-propelled impulses to the periphery. The typical example of this is the phantom limb, but many other types of peripheral trauma can be cited which finally reach a cortical level. In our material 6 patients have reached such a state from trauma in the extremities. One committed suicide, 2 are in institutions, 3 are addicted to morphine (table 4).

TREATMENT

The value of such segmentation of sensory neurons lies in the ability of selecting the proper level of attack for treatment. The early causalgic state, characterized by burning, throbbing pain relieved by suprasystolic compression of the limb, by elevation, by cooling or by moisture, is still localized to the area of stimulation. When the site of trauma, a digit, the ankle the wrist, is thoroughly infiltrated with 1 per cent procaine, not only are the sensory stimuli blocked but the secretion of the vasodilator substances is inhibited. Even though the anesthesia wears off shortly, the nonmyelinated fibers, which seem to be involved, are still paralyzed, since they are much more sensitive to procaine than the large myelinated sensory fibers.[11] The release of the protective muscle spasm, splinting the painful area, also adds to the relief from pain and allows early motion. If local infiltration fails to relieve the pain projected to that area, the stimulus has progressed to a higher level. If infiltration of an amputation neuroma does not relieve the painful stump or the phantom limb, a local excision is certainly not going to be of any benefit.

In the stage of a spreading neuralgia with which osteoporosis is frequently associated a block of the paravertebral sympathetics is advisable (figs. 2 and 3). It is surprising how much relief can be obtained in causalgias in this second stage of spreading hyperalgesia by repeated sympathetic block. In previous articles we[12] discussed the mechanisms whereby a block of the sympathetics which in itself produces vasodilatation is capable of relieving the painful vasodilatation of causalgia. All that can be said with assurance is that the causalgic type of vasodilatation is different from the one produced by heat, vasodilators or sympathetic block. It combines an increased pulse volume with an increased peripheral resistance, and sympathetic block abolishes this incoordination of vasomotor impulses (fig. 4).

* In reanalyzing the results obtained in former years, when a definite grading of the level of sensory irritation was not made, it is obvious that failure of recovery was invariably due to irreversible contractures or to a higher sensory level.

As Homans[13] pointed out, such repeated paravertebral blocks are capable of relieving the syndrome, but should it recur shortly after the block a sympathectomy, providing loss of vasomotor tone, is indicated.

My experience with sympathectomy in causalgia has not been extensive; it seems especially useful in the painful amputation stump when local infiltration does not help. Sympathetic interruption has helped to relieve the burning pain even in the presence of a lesion of the second neuron, suggesting that the pain, just as in the peripheral traumatic lesions, is due to a secretion of painful substances which the improved circulation is capable of neutralizing. Gesell and his associates[14] have shown how tissue acidity modifies nervous impulses by inhibiting the destruction of acetylcholine.

If sympathetic block fails to relieve the pain, sympathectomy should certainly not be undertaken. Posterior root section is not only mutilating but a dangerous procedure, since it adds the syndrome of "anesthesia dolorosa" to the causalgic state (table 5).

Cutting of the spinothalamic tract (chordotomy) seems the logical procedure for a lesion of the second neuron. There can be no question of the relief it provides in painful lesions of the lower extremity unless the pain has become a psychic projection of the cortex. This may be the reason why Bailey and Moersch [15] could not register any relief in their cases. There is insufficient experience as yet with chordotomies for the arm, although Stookey [16] has recently reported having done sixteen high cervical chordotomies for relief of pain in the arm and upper chest due to mammary carcinoma. No cases of causalgia are included.

The important question arises whether or not one can localize the level of sensory irritation by certain nerve blocks. In White's case of a right parietofrontal meningioma the opposite arm exhibited excruciating pain following operation. A brachial plexus block resulting in complete motor and sensory anesthesia did not reduce the pain. Such a procedure can readily differentate a painful syndrome of the first neuron from that of the third neuron. But the fact that a spinal anesthesia fails to abolish the pain from a phantom foot does not mean that sympathectomy will not help.

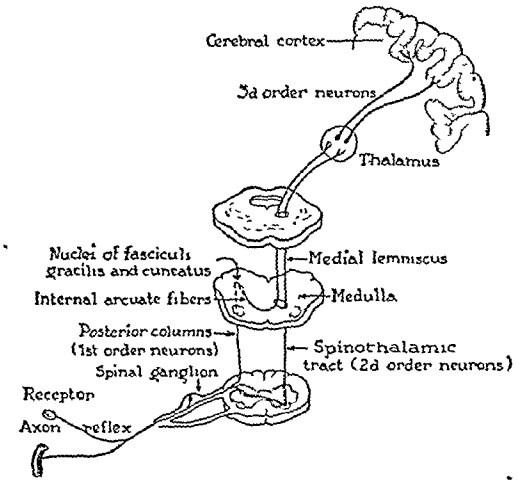

Fig. 1.—Diagram of three sensory neurons. The peripheral (first) neuron has its ganglion cell in the posterior root ganglion. The peripheral processes form the sensory fibers of the sensory nerves ending in special receptors in skin, muscle, tendon. The central processes pass through the dorsal roots into spinal columns, where they synapse with second order neurons. The spinothalamic tract constitutes the second order neuron connecting in the thalamus with the highest, third order neuron. Modified from McDonald, J. J., and Lange, J.: Correlative Neuroanatomy, ed. 2, Chicago, University Medical Publishers, 1939. Obviously, if pain persists after a procaine block of the first neuron, the irritative sensory lesion is at a higher sensory level.

This was the case in a man aged 53 with arteriosclerosis who lost his right leg in January 1943 and has had increasing pain in the phantom foot ever since. In January 1944 his left leg was amputated in my service at the Research and Educational Hospitals. Fifteen months after the first and three months after the second amputatioin he had bilateral phantom limb pain. The pain following the second amputation could be abolished by two infiltrations of procaine into a trigger zone. The pain following the first amputation, which kept him awake nights and culminated in attacks of stump epilepsy, could not be relieved by local infiltration or by spinal anesthesia to the level of the ninth dorsal. However, sympathetic block followed by lumbar sympathectomy completely freed him of pain on the right side.

If local infiltration, peripheral nerve block, sympathetic block and spinal anesthesia fail to relieve the causalgic pain, there remains a selection of tractotomies at different levels of the central nervous system. In a recent communication on pain after amputation, Capt. James C. White has enumerated these central procedures.[17] Walker [18] has given an illuminating description of the levels at which pain may be integrated in the cortex. The highest level is in the cortex, the second in the thalamus and the lowest at the tectum mesencephali. Mention should be made of Mahoney's bril-

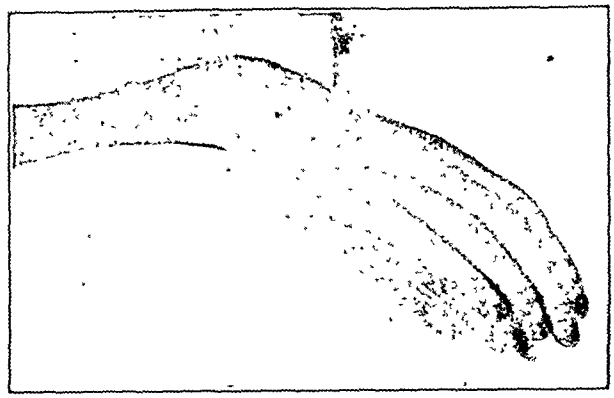

Fig. 2.—Case of H. L., a woman aged 24, a musician, who fell on the dorsum of her right hand while skating. No fracture or dislocation occurred. Burning, intractable pain was present from the start. She received much splinting, physical therapy and forced manipulation. Sympathetic blocks were started many months after the injury. This is the appearance of her right hand when first seen four years after the injury. The extensor muscles were so atrophic that active dorsiflexion was impossible, although the muscle reacted well to electrical stimulation. All the joints of the fingers were ankylosed in extension. The hand was cold and useless; it could be subjected to physical therapy only under the protection of a brachial plexus block. Functional recovery is not to be expected. Psychotherapy with rehabilitation is now under way.

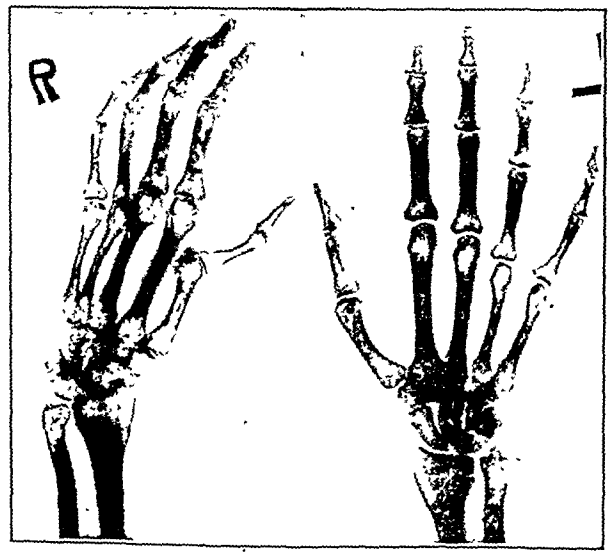

Fig. 3.—The affected right hand, with a control film of the left hand. Note the severe, spotty osteoporosis, showing some coarse trabeculation as an indication that the recalcification is under way. The joint spaces are narrow or obliterated. The atrophy of the ulnar extensors resulted in a deviation of the hand toward the radial side. The thumb shows a subluxation. It was not injured originally.

liant result with a phantom arm following the resection of the postcentral gyrus in December 1941. The relief persists to date.[19]

COMMENT

The puzzling vasomotor and trophic phenomena following the irritation of sensory pathways have been described in the past under a great many names. It has been previously pointed out [20] that Sudeck's atrophy, traumatic osteoporosis, peripheral trophoneurosis, reflex dystrophy, chronic traumatic edema, are all based on the same mechanism. To this group one may add a nontraumatic group of irritative lesions in any of the three sensory neurons, which are capable of producing a chronic, spreading hyperalgesia. In such a lesion a group of fibers is activated which secrete pain-producing, vasodilator substances at the nerve endings. Phantom limb pain may be reasonably added to this group of cases, although the evidence of vasodilatation, edema and trophic changes cannot be elicited in the nonexisting limb; however, the stump itself is often red, hot and tender. Heat and dependency aggravate the symptoms. The patient keeps his stump elevated and uncovered.[21] Whether the activated fibers are ordinary sensory fibers conducting in the opposite, efferent direction [4] or whether it is necessary to postulate a special set of posterior root fibers that produce vasodilatation [22] is not within the scope of this discussion. Nor is it clear whether the substance produced at the nerve endings is acetylcholine or histamine; both of these substances have been recovered after stimulation of posterior root fibers.[23] What one can state with assurance is that in the causalgic state, unlike in other painful states which lead to continuous afferent impulses, there is an efferent stimulation of pain-producing, vasodilator substances which unless blocked or neutralized early will lead to the sensitization of higher and higher levels. It has also been previously [24] pointed out that neostigmine, a cholinergic vasodilator, is capable of producing a type of vasodilatation exhibited by causalgia (fig. 5).

In this group of 54 cases there was no evidence that any definite type of personality was responsible for this unusual reaction to a sensory stimulus. But the study of the fundamental work of Bayliss [4] reveals that under certain conditions, such as weak stimuli, cooling of the nerve or regeneration of a partially injured nerve, the stimulation of a peripheral nerve results in vasodilatation with a simultaneous inhibition of the vasoconstrictors. He also showed that stimuli which usually produce pressor effects may have a reversal of their effect to vasodilatation under the influence of drugs which affect a higher level. Thus cocaine, which usually produces a vasoconstriction and a rise in pressure, will produce vasodilatation when preceded by strychnine.

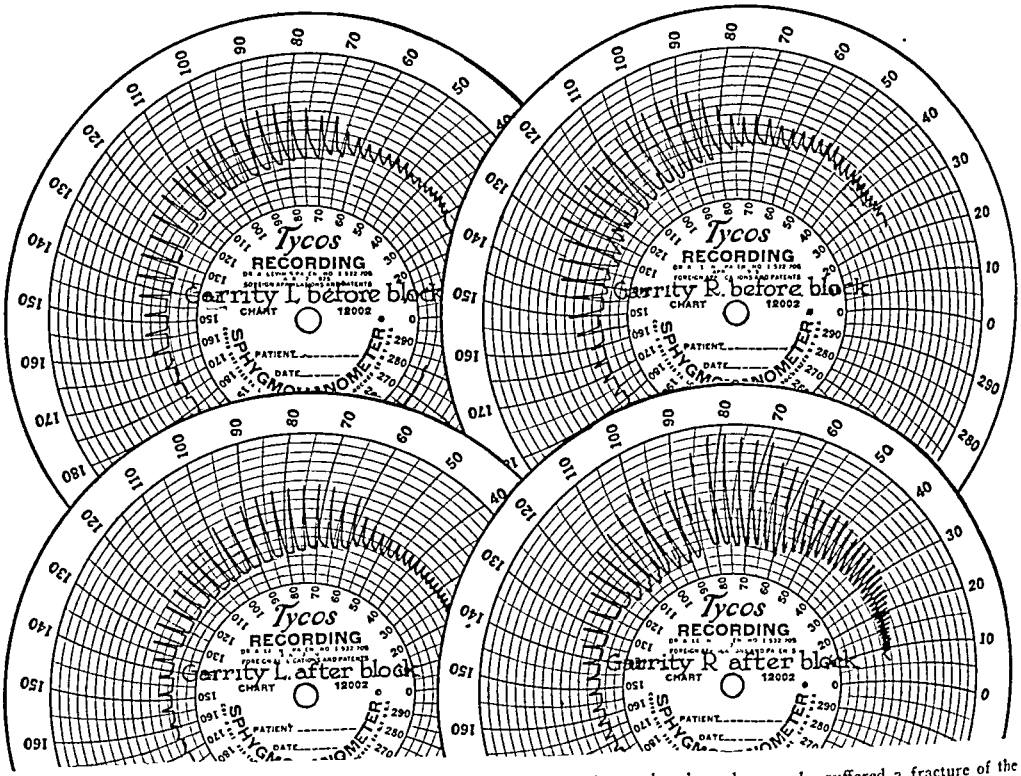

Fig. 4.—Oscillometric curves in the case of F. G., a man aged 55, a railroad employee, who suffered a fracture of the right fibula with an ankle sprain. The fracture was not recognized immediately and he walked on this foot for some time. Six months after the injury there was an area of anhidrosis with hyperesthesia corresponding to the distribution of the superficial peroneal nerve. . . . e showed much increased pulse waves between 150 and 80 mm. of mercury, as compared to . . . . . is a typical diminution of the waves at 75 mm. of mercury, which is quite sudden. The pain was th . . . . . ot was edematous and glossy. Cold, moist towels gave temporary relief. Twenty minutes after a . . . . . block there is an obvious increase in circulation. However, while the large spike at 125 mm. of mercury, seen before the block, is now absent, the maximal pulsations have shifted toward the right, toward lower pressures, reaching their maximum between 85 and 70 mm. of mercury. The decrease toward lower pressures is gradual. Pain completely disappeared for forty eight hours. After a few blocks pain was completely abolished and weight bearing resumed. This is the typical vascular reaction of a causalgic state (first stage) to a sympathetic block.

These findings have an immediate bearing on the problem at hand. They indicate that the causalgic state, as in the experimental animal, is a state of reversal from a normal vasomotor reaction and that this reversal is brought about by a changed state either of the peripheral nerve or of the higher centers. The character of the injury, namely pressure, traction or contusion, may be responsible for this peculiar phenomenon.

SUMMARY

The causalgic state is due to a chronic irritation of sensory pathways producing cutaneous hyperalgesia, burning pain and a local increase in blood flow. Three

sensory level and a cortical, can be clinically becomes more and more intractable the higher it ascends. In the first stage local infiltration and block of the paravertebral sympathetic nerves are effective. At the second level anterolateral chordotomy has been most helpful. The treatment of the third stage with cerebral tractotomies or removal of the sensory cortex is still in its infancy. Early diagnosis and immediate treatment saves much suffering and eliminates permanent disability. The true hysterical lesion shows no vasomotor changes except those due to immobility.

ILLUSTRATIVE CASE HISTORIES

LESIONS OF THE FIRST NEURON

CASE 1.—F. G., a man aged 56, a conductor, injured his right leg on Dec. 21, 1942. At first an ankle sprain was diagnosed, but after a few days a fracture of the upper third of the fibula was identified by x-ray. A cast was applied but had to be removed in four days because of severe burning pain and edema. Neither moist nor dry heat relieved the pain. Ice packs gave some help. Deep phlebitis was suspected because of the edema. He was unable to bear weight on this leg because of severe pain and had been hospitalized for several months at a time. Examination July 3, 1943, seven months after the injury, revealed an erythematous, swollen right lower leg. He had good evidence of a deep venous thrombosis, but the oscillograms (fig. 4) and the pronounced osteoporosis suggested a causalgic state. The skin was warm and dry along the distribution of the superficial peroneal nerve, cold, moist and clammy around this area, a marginal hyperhidrosis. Following repeated lumbar sympathetic blocks he was able to get up and walk around bearing weight on the right leg, which he had been unable to do for seven months. He was discharged on July 31, 1943 with an elastic hose, with ability to walk around without crutches. The skin temperature remained increased for a year after the injury. He returned to limited duty but was found to suffer from an inoperable carcinoma of the stomach in the middle of May 1944.

Because of the fracture and the consecutive deep venous thrombosis the injury to the superficial peroneal nerve was missed by many observers. The patient was regarded as a malingerer, which made him defiant and ready to file suit. A simple clinical examination and repeated lumbar sympathetic blocks restored his earning power.

CASE 2.—M. P., a woman aged 25, admitted Jan. 26, 1943 and discharged Feb. 6, 1943, developed blisters on the fingers of the right hand while stripping cables, three months before admission. Her right hand became infected, and red streaks spread up from the wrist to the axilla. She was treated with hot fomentations and sulfadiazine at another hospital, and the acute infection subsided. However, a burning type of pain persisted which was aggravated by heat and dependency, alleviated by moist cold and elevation. Oscillometric curves showed increased peripheral resistance on the right side, right 5/100, left 5/80. Following block of the stellate ganglion the right arm and hand became dry and a complete Horner's syndrome developed. The oscillations increased but the pain and stiffness were relieved. There was no osteoporosis. She was given x-ray therapy to the right axilla: 125 kilovolt peak, 20 milliamperes, 50 cm. focal distance, ¼ copper 1 aluminum filter, 105 roentgens. She was readmitted a month later with a multiplicity of symptoms. She cried easily and had fainting spells. Dr. Francis Gerty found a suggestible, psychoneurotic background. She was quite anemic. Following some occupational therapy the pain and vasomotor symptoms in the arm were fully relieved. She has been said to have started suit against her employer.

Here is a psychoneurotic individual in whom an attack of acute lymphangitis acted like a trigger to bring out a variety of symptoms. There was, however, objective evidence of nerve irritation. A perineural lymphangitis may well produce a in the case of a radial nerve injury c in which the causalgia started after the wound became infected and erysipelas set in.[1]

CASE 3.—P. T., a man aged 42, admitted on Dec. 27, 1943, complained of anxiety regarding his health, "excessive warmth" of the left arm and pain under the inferior angle of the left scapula and the inner aspect of the left arm as far as the elbow. The pain was relieved by elevation. Night sweats and dizziness also were present. An electrocardiogram and chest films were said to be negative. The left arm and hand were noticeably warm and dry but not flushed. There was a Horner's syndrome on the left. Oscillations greatly increased but showed

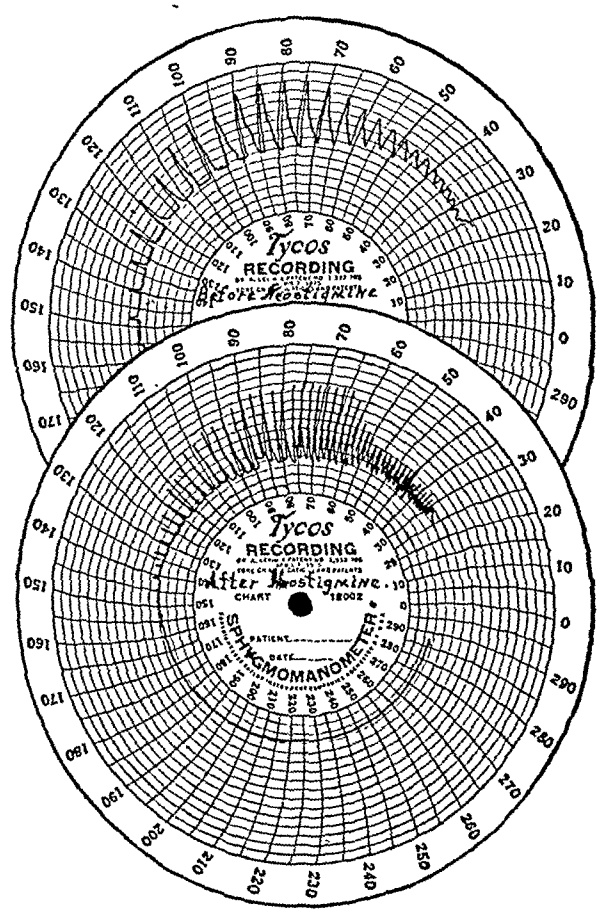

Fig. 5.—This patient, with a normal cardiovascular status, received 1 mg. of neostigmine subcutaneously together with 0.5 mg. of atropine sulfate to counteract the side effects. It is known that atropine will not affect the cholinergic vasodilatation produced by neostigmine. Note that one-half hour after the injection of neostigmine there is a striking rise of peripheral resistance at 60 mm. of mercury. The rise in pulse waves occurs between 90 and 60 mm. of mercury. This is the type of vasodilatation seen in causalgic states, which differs greatly from that following sympathetic paralysis or the administration of sodium nitrite.

increased peripheral resistance. Motor and sensory nerves were intact. X-ray examination revealed a tumor of the left apex.

On Jan. 19, 1944 left upper lobectomy was performed by Dr. W. Van Hazel. The tumor was seen to invade the first and second intervertebral foramens. A small portion of the tumor could not be removed. Intensive x-ray therapy was given shortly after the operation.

The severe causalgic pain continued after the operation. He rapidly went down-hill and died in April 1944. His first and

dominant symptom was the causalgic type of pain of the left arm due to irritation of the posterior roots and ganglions at the intervertebral foramens.

LESIONS OF THE SECOND NEURON

CASE 4.—J. K., a woman aged 39, admitted Nov. 23, 1941, had had severe poliomyelitis in South America in 1936 affecting the right arm, right jaw and left leg. Slight motor weakness remained but also a nagging, throbbing pain, relieved by elevation and cold, exaggerated by heat. There was also muscle twitching in the left leg, mostly at night.

The left leg was slightly atrophic, with partial foot drop. It was colder at room temperature, hotter and swollen in warm weather. The oscillometric readings were increased on the affected side. There was a diffuse hyperalgesia and a constricting type of pain around the thigh, which increased on fatigue. There was a weakness of the internal hamstrings. The faradic current gave a moderate feeling of warmth on the right and a sharp, lancinating pain on the left. Since the histamine flares were diminished, it was thought that perhaps the posterior root ganglions were involved. Treatment consisted of intravenous thiamine hydrochloride, x-rays to the paravertebral ganglions and sympathetic block. She was discharged Dec. 3, 1941 greatly improved.

This was a patient with a known infectious involvement of the cord producing causalgic pain, relieved by paravertebral block. Such cases of painful poliomyelitis are not infrequent.

CASE 5.—L. C., a man aged 22, a sailor, developed scarlet fever after a submucous resection. He received sulfonamide drugs. An erythema nodosum followed and, shortly after, pain and numbness developed in the right foot and left arm. Six months later there were attacks of coldness and cyanosis, alternating with rubor, edema and throbbing pain in the affected extremities. There was pronounced osteoporosis in the right foot and an oscillogram was obtained revealing increased pulsations with increased peripheral resistance. There was some loss of motor power and a partial foot drop. Because of a suspicion that periarteritis nodosa might be present, an exploration of the posterior tibial vessels and nerve was undertaken with a negative result. Following repeated sympathetic blocks, and aided by a cast with an incorporated walking iron, he was able to get up and bear weight on the painful extremity. A tentative diagnosis of an acute disseminated myelitis was made (Dr. R. P. Mackay). A follow-up inquiry revealed gradual improvement with some loss of motor power.

The cord lesion here was of questionable origin, although the infectious or allergic nature of disseminated vascular lesions of the cord is not unknown. As soon as weight bearing was started, made possible by the sympathetic block, a turn for the better ensued.

LESIONS OF THE THIRD NEURON

CASE 6.—A. F., a man aged 75, a retired executive, suffered an attack of cerebral thrombosis in May 1939. A left hemiplegia developed with a gradual return of motor power. However, the paralyzed left limb became agonizingly painful, with intermittent exacerbations of lancinating pain. During such attacks the oscillations increased and the skin temperature rose. Nothing was found to relieve the pain effectively. Between attacks a pronounced dysesthesia was present. He died three years after the initial vascular accident.

This pain was certainly central, whether thalamic due to cortical release or cortical due to an irritative lesion is uncertain. The attacks of vasodilatation accompanying these sensory jacksonian fits place this pain among the causalgic states.

122 South Michigan Avenue.

ABSTRACT OF DISCUSSION

DR. WARREN H. COLE, Chicago: Insufficient time has elapsed since our entry into the war for us to obtain accurate data from war casualties on the incidence of this condition. A German report of 2 cases of causalgia in 500 cases of nerve injury (Reichert: *Bull. War Med.* **3**:379, 1942) probably represents an average incidence. However, it must be emphasized that the etiologic factors are extremely numerous, many cases developing when the role of nerve injury would appear insignificant. The most impressive case which has come to my attention developed two or three weeks following a relatively mild ankle sprain in a person with no neurotic or hysterical tendencies. Although it may be difficult on many occasions to differentiate this condition from malingering states, the presence of a warm, shiny and pink skin along with increased blood flow should readily make the differentiation. The warm and pink surface may change to a cool and cyanotic skin. Unfortunately, treatment is by no means satisfactory. Early in the disease the patient learns that keeping the affected limb elevated, cool and moist adds to comfort. Even though this simple therapy may be quite effective, it cannot be adopted as the sole and permanent therapy because of the serious dangers of mental deterioration developing as the disease progresses. I know of no definite evidence that these mental changes predispose to the disease; it appears much more logical to me that the extreme pain and disability suffered week after week and month after month would be the primary factor in development of the mental deterioration. The possibility of development of serious mental changes more than justifies the philosophy that therapy must be carried out with minimal delay even though it may appear quite radical. Sympathetic block (including sympathectomy) appears to be accepted quite generally as offering the best chance of obtaining relief. At times, frequent blocks with procaine will result in permanent relief. Dr. de Takats correctly emphasized the fact that sympathectomy should not be performed if procaine block is ineffective in relieving pain. Neurolysis has been reported frequently as being effective and should be considered particularly when there appears a strong probability that the nerve was crushed or otherwise damaged.

EFFECTIVENESS OF PENICILLIN IN THE TREATMENT OF VINCENT'S ANGINA

CAPTAIN BERNARD M. SCHWARTZ
MEDICAL CORPS, ARMY OF THE UNITED STATES

The effectiveness of penicillin as an antispirochetal agent in the treatment of syphilis,[1] relapsing fever,[2] Weil's disease[3] and rat bite fever[4] has prompted a study of its use in Vincent's infections.

For this study, only patients with Vincent's angina have been selected because Vincent's infection of the tonsil, although subject to recurrence, is an acute illness and is almost always a primary infection. Where it is not, the underlying cause, such as a blood dyscrasia, is evident. On the other hand, Vincent's gingivitis is much more apt to be a chronic or frequently recurrent illness, often associated with dental abnormalities or faulty

nutrition, and its treatment entails proper dental or vitamin therapy as well as antispirochetal measures. True evaluation of chemotherapy for Vincent's gingivitis, therefore, is difficult and a long follow-up period is necessary.

Fourteen cases of Vincent's angina have been treated with penicillin at this hospital, as summarized in the table. Diagnosis was established by positive clinical and laboratory findings. Clinically the local lesions on the tonsil or pharynx had the following features in varying severity and combination: hyperemia, ulceration, exudation (pseudomembrane), bleeding, characteristic odor, submaxillary lymphadenopathy, edema and associated mild gingivitis. One patient had a temperature of 101.2 F. (oral). The others either had slight fever (99-100 F.) or were afebrile. Symptoms in every case were pronounced. Pain in severe cases was so intense that solid food was refused. In some instances the symptoms were out of proportion to the physical findings.

In each case a dried smear of exudate from the lesion was positive for Borrelia vincenti. No smear was considered positive unless there was an unequivocal profusion of characteristic spirochetes and fusiform organisms present. In addition, in several cases, throat culture was negative for other pathogenic organisms. The differential leukocyte counts revealed no abnormal cells.

Penicillin was injected intramuscularly in each case. The intramuscular route was chosen in preference to local application for several reasons. Studies of the effect of penicillin on other micro-organisms have shown that it exerts its maximum effect after six to eight hours of contact.[5] Without knowing the length of time locally applied penicillin remains in contact with mucous membranes, one would find it hard to advise rational dosage schedules. The ease with which locally applied penicillin will penetrate to the depths of an exudate covered ulcer is unknown. Furthermore, it has been shown that parenterally injected penicillin is secreted in the saliva.[6] Thus, when the intramuscular route is employed the deep portions of the local lesion will be constantly attacked by penicillin conveyed in the blood stream while the superficial portions will be continually bathed by the penicillin present in the saliva.

The first 2 patients to be treated were given a total of 200,000 units of the sodium salt of penicillin administered in 20,000 unit doses every three hours intramuscularly. The response was so satisfactory that all subsequent cases, with 3 exceptions, had the dosage reduced to 100,000 units administered in 20,000 unit doses every three hours. The 3 exceptions were as follows: In 1 moderately severe case two doses of 50,000 units were given six hours apart, and in 2 mild cases a total of 50,000 and 25,000 units was given in one dose, respectively. Although the response in these 3 cases was satisfactory, it was deemed advisable to continue this study with doses of 100,000 units (20,000 units every three hours) because the smaller doses given were found to be only temporarily effective in cases of Vincent's gingivitis being observed at about the same time.

The result in each case treated was satisfactory. In every instance subjective discomfort was decidedly alleviated in twenty-four hours and completely eliminated in forty-eight hours. There was definite improvement within four to six hours. In every instance the smear which was positive before treatment became negative after treatment. Ten of 11 patients who had smears taken within twenty-four hours after the onset of treatment had negative smears at this time. The eleventh patient, who had received only 25,000 units, had a positive smear remaining after twenty-four hours but, without further penicillin or other therapy, had negative smears in forty-eight, seventy-two and ninety-six hours. The remaining 3 patients, whose clinical response was in every way similar to the foregoing 11, had negative smears two, three and nine days after treatment, respectively.

The appearance of the lesions also improved remarkably, although this improvement was not as dramatic as the relief of subjective symptoms and the disappearance of the organisms from the smears. The first effect, noted within twenty-four hours, was a change in the color and character of the exudate. The usual change was from a dirty gray or yellow membrane which bled easily to a clean whitish gray film which did not bleed. The offensive odor disappeared in twenty-four hours. The exudate and ulcer required from one to ten days for complete disappearance, depending on the initial severity of the lesion. Simultaneously, adenopathy gradually subsided. When present originally, gingivitis rapidly disappeared. The temperature was invariably normal after twenty-four hours. No recurrences have been observed.

5. Keefer, C. S.; Blake, F. G.; Marshall, E. K.; Lockwood, J. S., and Wood, W. B.: Penicillin in the Treatment of Infections. A Report of 500 Cases, J. A. M. A. **122**: 1217-1224 (Aug. 28) 1943.

6. Abraham, E. P.; Chain, E.; Fletcher, C. M.; Gardner, A. D.; Heatley, N. G.; Jennings, M. A., and Florey, H. W.: Further Observations on Penicillin, Lancet **2**: 177-188 (Aug. 16) 1941.

The results demonstrate that penicillin is an effective agent in the treatment of Vincent's angina. From my own experience it is definitely superior to hydrogen peroxide or sodium perborate gargles. Several of the patients had received these medications before penicillin was started with slight or no improvement and continued positive smears after twenty-four to forty-eight hours. The rapidity with which penicillin acts should be of value in reducing the loss of man hours in military and civilian life, in decreasing contagiousness and in reducing the period of discomfort for the patient.

Schuessler, Fairchild and Stransky [7] and Strock [8] have found penicillin in the form of spray or mouth wash to be effective in the treatment of Vincent's stomatitis. Barr,[9] in a summary of results of penicillin therapy in the Navy, records 4 cases of Vincent's infection successfully treated, without further details. Denny, Shallenberger and Pyle [10] have also found penicillin effective for Vincent's infections. It should be pointed out that when Denny and his associates applied penicillin solutions in a concentration of 250 units per cubic centimeter to tonsillar lesions the smears became negative in three days, but in the 1 case in which they gave penicillin intramuscularly smears were negative within twenty-four hours. It would seem, from my experience, that the total dosage of 520,000 units given in this case was greater than is necessary. In a recent case of severe fusospirochetal balanitis treated by Capt. W. F. Schwartz,[11] at this station, 200,000 units of penicillin in a period of forty-eight hours resulted in a dramatic cure. The patient had subjective relief in four hours, and the inflammation had subsided about 80 per cent in twenty-four hours.[12]

SUMMARY AND CONCLUSIONS

1. Penicillin has been found to be of definite value in the treatment of Vincent's angina in 14 cases.

2. The recommended dose is 100,000 units administered intramuscularly in 20,000 unit doses every three hours. In mild cases smaller doses may be required and in unusually severe cases larger doses may be required.

12. Since the submission of this article for approval for publication, the total number of cases treated has risen to 41, with similar results. Among these have been 3 cases of infectious mononucleosis with secondary Vincent's tonsillitis and gingivitis. Penicillin has had no effect on the course of the infectious mononucleosis but has eliminated the Vincent's infection.

Natural Control of the Black Widow Spider.—Enemies of the black widow spider should be encouraged to propagate and multiply. Those parasitic insects which pray on Latrodectus mactans should be permitted to roam unhampered in their outdoor habitats, and increasing efforts must be made to evaluate their spider-destroying propensities. The mud-dauber's nest, heretofore considered only as an evidence of untidiness, may now be accepted as indicative of human enlightenment, the abode of a known destroyer of the world's most poisonous arachnid. An appalling record of human suffering has been double-checked back to Latrodectus mactans and her prototypes. There is no appeal from the indictment, and mankind must now make a unified effort toward curtailment of the greatest arachnid menace the world has ever known.—Thorp, Raymond W., and Woodson, Weldon D.: Black Widow—America's Most Poisonous Spider, Chapel Hill, University of North Carolina Press, 1945.

THE USE OF PENICILLIN IN VINCENT'S ANGINA

MAJOR PAUL L. SHALLENBERGER
LIEUTENANT COLONEL EARL R. DENNY
AND
MAJOR HAROLD D. PYLE
MEDICAL CORPS, ARMY OF THE UNITED STATES

The chemotherapeutic effects of penicillin in certain spirochetal infections have been successfully demonstrated in human subjects and in experimental animals.

Mahoney [1] was the first to demonstrate the spirocheticidal effect of penicillin. In a careful and well planned study, he observed the disappearance of Treponema pallidum from scrapings of chancres after fourteen hours of treatment using 25,000 units intramuscularly at four hour intervals. Furthermore, the duration of the primary ulcerations was only eight days. We confirmed these observations by using penicillin in doses of 25,000 units every three hours on 2 patients with primary chancres. The dark field examinations were positive through the eighth hour following the institution of treatment, but specimens obtained at twelve hours did not contain Treponema pallidum. O'Leary and Herrell [2] observed a rapid disappearance of the late cutaneous manifestations of syphilis, following continuous intravenous drip of 20,000 units of penicillin twice daily.

Penicillin is highly effective against other types of spirochetes, as clearly shown in experimentally produced Leptospira icterohemorrhagiae infection in guinea pigs. In February 1944 Heilman and Herrell [3] reported their investigations with penicillin in experimental Weil's disease. In 64 guinea pigs infected with Leptospira icterohemorrhagiae 32 were treated intramuscularly daily for seven days with 800 units of calcium penicillin suspended in sesame oil. Of these 32 guinea pigs none died of the disease, although 3 died from toxic effects attributed to penicillin. Twenty-nine of the 32 untreated control animals died of Weil's disease.

Penicillin is not, however, equally effective against all strains of Leptospira icterohemorrhagiae. Augustine and his associates,[4] using a virulent strain, found that penicillin did not cure the disease in guinea pigs if treatment was started after the appearance of the symptoms. That pencillin may exert some suppressive effect is suggested by survival of some inoculated animals if treatment was started prior to the appearance of signs of the disease.

In view of the spirocheticidal potentiality of penicillin, one of us (P. L. S.) suggested that penicillin might be of value in the treatment of infections due to or associated with Vincent's organisms. In a previous report [5] our clinical and bacteriologic observations indicated that penicillin was indeed highly effective in the treatment of Vincent's infection.

Mr. J. W. Crunelle, head of the [illegible] University of Chicago, made the photomicrograp[illegible] Marzec and Miss Catherine J. Vanderboom, Gar[illegible] made the major portion of the bacteriologic examinations.

METHOD OF STUDY

The present study is based on adult patients suffering from Vincent's infections admitted to the communicable disease section of the Gardiner General Hospital.

The diagnosis of Vincent's angina was established in each patient by the findings of a patch or patches of pseudomembrane which is formed by the necrosis of the superficial layers of the mucous membrane and not by exudation. The patches were grayish white surrounded by an inflamed areola, usually separated from one another by normal healthy tissue. When the pseudomembrane, which was granular and cheesy in consistency, was removed an underlying ulcerative area was found with some variation in extent and depth. There was a tendency for the ulcerated area to bleed and the reformation of a new pseudomembrane. The areas involved were often confined to one or both of the tonsils, the tonsillar fossae if the tonsils had been removed, the pharynx or the soft palate. The clinical diagnosis was confirmed by making a microscopic examination of a fresh smear taken directly from the ulcer or the scrapings from the pseudomembrane, stained with warm carbolized crystal violet, demonstrating fusiform bacilli which were twice as long as they were wide, pointed at the ends, and a spirillum approximately 10 to 20 microns in length. From each patient of groups 3 and 4 cultures were obtained to exclude other pathogens, such as hemolytic streptococci.

The patients were divided into four groups. Group 1 consisted of 13 patients admitted during November and December 1943 who were treated variously with hydrogen peroxide, sodium perborate, chromic acid, silver nitrate and oxophenarsine hydrochloride (mapharsen). Most of this group were treated by swabbing the involved areas three times daily with a mixture of 3 per cent chromic acid and 10 per cent silver nitrate, preceded by gargling a mixture of equal parts of 50 per cent sodium perborate and 50 per cent hydrogen peroxide. A few of the patients received, in addition to this treatment, and others alone, 0.03 Gm. of oxophenarsine hydrochloride intravenously every second or third day.

Group 2 consisted of 11 patients admitted during January and February 1944 who were treated with 1 Gm. doses of sulfadiazine, used as lozenges, every four hours.

Group 3 consisted of 9 patients admitted subsequent to February 1944 and treated with penicillin by local application. The following method was used: 1. The involved tissues were swabbed with penicillin in a concentration of from 250 to 500 units per cubic centimeter four times daily. 2. Daily smears were obtained. 3. Treatment was continued until the smears were negative for Vincent's organisms.

No other supportive treatment was administered, although acetylsalicylic acid 5 grains (0.32 Gm.) was given as indicated for the relief of pain.

As the investigation progressed, concentrations of the penicillin solution used were maintained at 500 units per cubic centimeter.

Group 4 consisted of 2 patients treated with penicillin administered intramuscularly alone. One of those was treated with penicillin intramuscularly because his symptoms were unusually severe. In order to determine the clinical and bacteriologic effectiveness of penicillin following intramuscular administration, the second patient of this group was subjected to detailed study. The procedure in investigating this patient was as follows: (1) Culture and (2) warm carbolized crystal violet stained smears of the lesions were made on admission; (3) 15,000 units of penicillin in a concentration of 10,000 units per cubic centimeter was administered intramuscularly every three hours for eight doses; (4) following the institution of penicillin treatment estimates of the number of Vincent's organisms on stained smears were made hourly for twelve hours and subsequently at less frequent intervals, as indicated in figure 2; (5) the changes in objective and subjective symptoms were observed at the time specimens were obtained for bacteriologic examinations.

THERAPEUTIC RESULTS IN CONTROL GROUPS

Prior to January 1944 it was common practice to apply directly to the affected areas astringent agents and other medicinals which liberated nascent oxygen. As already noted we used mixtures of chromic acid and silver nitrate, sodium perborate and hydrogen peroxide, and in some cases oxophenarsine hydrochloride with this treatment, and in others alone. The summary of these cases is presented in figure 1. It is to be noted that in this group most of the smears did not become negative until the seventh to the twelfth day.

During January and February 1944 we began using 1 Gm. doses of sulfadiazine every four hours adminis-

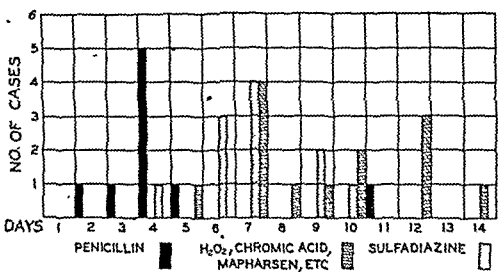

Fig. 1.—Comparative therapeutic effect in Vincent's infection of (1) hydrogen peroxide, chromic acid, oxophenarsine hydrochloride and so on and (3) penicillin. The ordinate indicates the number of cases. The abscissa indicates the days on which smears became negative for Vincent's organisms.

tered as lozenges. There were 11 cases treated by this method. In most of the cases the smears became negative for Vincent's organisms by the seventh or ninth day.

THERAPEUTIC RESULTS WITH LOCAL APPLICATIONS OF PENICILLIN

In group 3 the clinical and bacteriologic responses as obtained with local penicillin therapy were very striking. There was improvement in the appearance of the ulcerations in twenty-four to forty-eight hours and a relatively rapid subsidence of the symptoms. Pain was rapidly relieved in those patients who were suffering severely. The grayish membrane would often start receding in from three to five days from the beginning of treatment. The organisms disappeared frequently before the pseudomembrane faded. The rate at which the organisms disappeared from the infected site is indicated in figure 1. With the exception of 1 case, the infecting organisms disappeared from the site of infection by the fifth day. Excluding this 1 case, which persisted in giving a positive smear, although clinically much improved by the fourth day, the average time of disappearance of Vincent's organisms was 3.7 days following the institution of penicillin therapy.

A soldier was admitted with huge swollen red tonsils, pharyngeal injection, painful throat and fever. The cultures of the tonsils showed beta hemolytic strepto-

cocci, and smears revealed large numbers of fusiform bacilli and spirochetes. He was given sulfadiazine lozenges and on the second hospital day he developed a grayish white membrane over both tonsils. He continued to complain of painful throat. During the succeeding two days the cultures became negative for hemolytic streptococci but the smear remained positive for Vincent's organisms in large numbers. Sulfadiazine

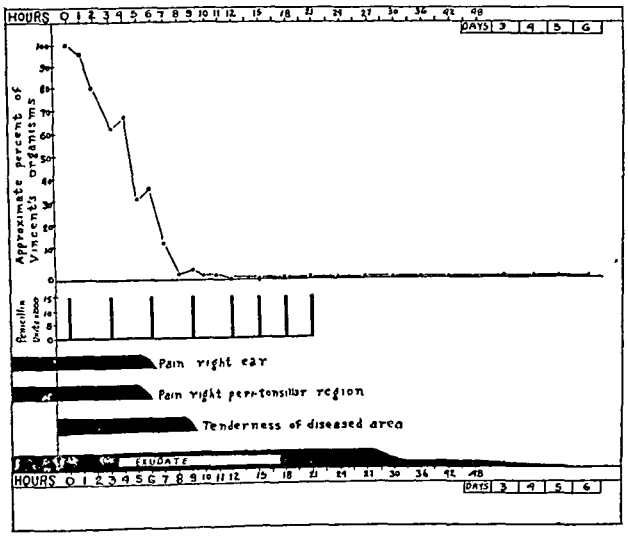

Fig. 2.—Approximate percentage in Vincent's angina of Vincent's organisms, penicillin dosage and the duration of referred pain to the right ear, the pain in the right peritonsillar region, the tenderness of the diseased area and exudate over the ulcer chronologically.

was discontinued. Local penicillin therapy was started. On the third day of this treatment the smears were negative and he was clinically well.

In group 4 intramuscular penicillin was administered to 1 patient who was acutely ill with Vincent's angina because of the severity of the disease. This patient had a temperature of 103.8 F. with hot, moist, flushed skin, a pulse rate of 110 and pronounced injection of all the gum margins, the tonsils and the pharyngeal wall. There was considerable edema with an occasional patch of loosely attached grayish membrane, over the tonsils and pharyngeal wall, which bled on separation. The submaxillary lymph nodes were enlarged and painful. The pain was severe. He was given 25,000 units intramuscularly followed with 15,000 units intramuscularly every three hours for thirty-three doses. An alpha hemolytic streptococcus was obtained on culture, but the predominating organisms were fusiform bacilli and spirilla of Vincent's organisms. Spirilla and fusiform bacilli persisted on the second day of treatment, but on the third day of treatment repeated smears showed no evidence of the organisms. There was definite clinical improvement within forty-eight hours.

The second patient in group 4 who was studied in considerable detail was a soldier aged 23 who five and two days prior to entry developed pain in the right peritonsillar area and pain in the right ear respectively. These symptoms became progressively more severe. Moderate fatigue developed two days prior to entry. On admission the significant findings were as follows: The tonsils had been removed. An ulcer, approximately 1 by 2 cm. covered by a grayish white membrane surrounded by edematous hyperemic mucosa, was present in the right tonsillar fossa. There was moderate hyperplasia and redness of lymphoid tissue on the posterior pharyngeal wall. The buccal and gingival mucosa appeared normal. The right submaxillary gland was slightly enlarged and tender. The findings on otoscopy were normal, indicating that the pain in the right ear was referred from the diseased right tonsillar area. The complete blood count was normal. Culture of the lesion showed only a few hemolytic streptococci, Lancefield type C, but direct smear revealed innumerable fusiform bacilli and spirilla. The therapy and subsequent bacteriologic studies described are recorded in figure 2. By the sixth hour after the first dose of penicillin, pain in the right peritonsillar area and the right ear ceased and tenderness in the right peritonsillar region stopped two hours later. There was less edema about the lesion twenty-four hours after the start of treatment. At forty-eight and seventy-two hours the size of the ulcer and pseudomembrane had diminished progressively. The latter gradually faded and disappeared on the ninth day.

In estimating the rapidity with which the Vincent's organisms disappeared following treatment, the smear taken prior to the institution of treatment was presumed to represent 100 per cent. The injection of 15,000 units of penicillin resulted in a reduction of approximately 40 per cent of the organisms in three hours; following a second 15,000 unit treatment an additional 25 per cent reduction of organisms resulted three hours later; two hours after the third treatment, or eight hours after the first treatment with penicillin, fusiform bacilli and spirilla could be found only by searching several fields on the slide. Twelve hours after starting treatment, or after the patient had received 60,000 units, fusiform bacilli and spirilla completely disappeared from

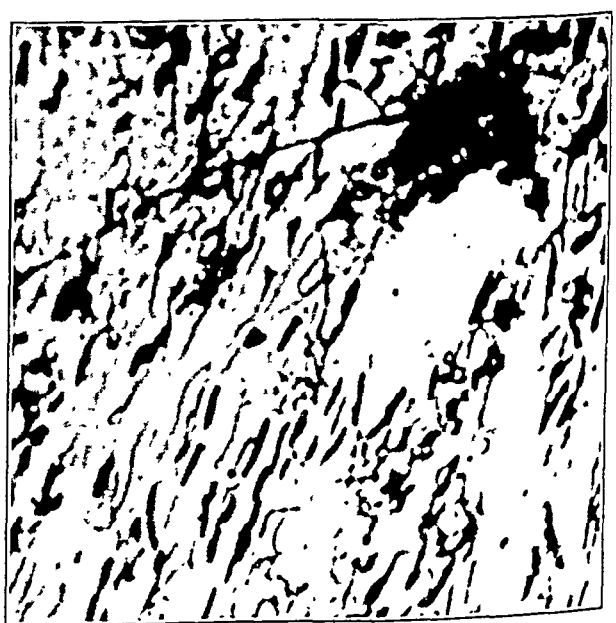

Fig. 3.—Organisms present immediately before the first injection of penicillin.

the site of infection, and subsequent examinations during the next five days resulted in negative findings as indicated in figure 2.

CYTOLOGIC FINDINGS

The photomicrographs taken immediately before the first injection of penicillin (fig. 3), the one taken three hours later (fig. 4) and seven hours later (fig. 5) clearly demonstrate the rapid disappearance of the

organisms. Only 7 fusiform bacilli and 1 spirillum are seen in the smear taken seven hours after the institution of treatment.

COMPARATIVE THERAPEUTIC RESULTS

The comparative therapeutic results as obtained with sodium perborate and hydrogen peroxide, chromic acid and silver nitrate, and oxophenarsine hydrochloride

Fig. 4.—Appearance three hours later.

(group 1), with sulfadiazine as lozenges (group 2) and with local penicillin (group 3) are shown in figure 1.

In group 1, consisting of 13 patients, there were none in whom the smear became negative before the fifth day, and in 3 patients the smear did not become negative until the twelfth day and 1 was not bacteriologically free until the fourteenth day of treatment. The average time before the smear became negative was 8.8 days.

Eleven patients (group 2) were treated with sulfadiazine lozenges. The smears of 1 patient became negative for Vincent's organisms on the fourth day, and 1 received treatment for ten days before the smear finally became negative. In this group treated with sulfadiazine lozenges the average time of disappearance of Vincent's organisms from the smears was 7.1 days.

The patients treated with penicillin locally (group 3) responded much more rapidly, as indicated in the chart. Smears were negative before the sixth day in all patients except 1, and this patient was clinically well on the fourth day of penicillin treatment with a large reduction in the number of Vincent's organisms found in the stained slide. However, occasional Vincent's spirilla and fusiform bacilli were seen on the smears on the eleventh day. Excluding this 1 case the average time of disappearance of the organisms from the smear was 3.7 days.

The patient in group 4 who received 15,000 units of penicillin intramuscularly every three hours for eight doses made the most rapid response to treatment of any of the patients in the first three groups. Following the initial treatment subjective symptoms disappeared in six hours and tenderness ceased in eight hours; the smears became essentially negative in eight hours, and fusiform bacilli and spirilla could not be found after eleven hours.[6]

COMMENT

The present clinical study demonstrates that penicillin is a remarkably effective agent in the treatment of Vincent's infection.

The efficacy of penicillin in Vincent's angina is of importance not only because of special sensitivity of Vincent's spirilla and fusiform bacilli but also because it is more rapidly effective than the methods heretofore advocated.

A favorable response was obtained in all cases treated locally. The only bacteriologic failure occurred in a patient who had organisms of Vincent's persist even after eleven days of local treatment, although the patient was clinically cured on the fourth treatment day.

In 1 case the effect was dramatic in that the subjective symptom of pain disappeared within six hours after the start of intramuscular treatment. The fact that symptoms disappeared within six hours after the onset of therapy and that the hourly quantitative bacterial study showed a rapid disappearance of the Vincent's organisms while receiving 15,000 units of

Fig. 5.—Appearance seven hours after the institution of treatment.

penicillin intramuscularly every three hours for eight doses suggest that this is a rapidly effective method of treatment of Vincent's angina. The duration of hospitalization was much reduced by this method of treatment when compared with sulfadiazine lozenges.

6. Subsequent to the time this paper was forwarded to the publisher, 2 additional cases, similar to the second case in group 4, have been observed. The treatment consisted in the intramuscular injection of 25,000 units and 20,000 units, respectively, administered every three hours for a total dosage of 100,000 units. The bacteriologic and clinical responses were so dramatic that the administration of 25,000 units of penicillin for four doses at three hour intervals is apparently the optimal treatment of Vincent's angina.

hydrogen peroxide and sodium perborate, chromic acid and silver nitrate, and oxophenarsine hydrochloride therapy.

The experience with this group of cases seems to justify the conclusion that topical application of penicillin in a concentration of 500 units per cubic centimeter applied four times daily is completely and rapidly effective therapeutic procedure in the treatment of Vincent's infection. As a result of our detailed study of 1 patient during the administration of 15,000 units every three hours for eight doses, it is suggested that this method of treatment warrants extended trial.

OXYGEN TOXICITY

THE EFFECT OF INHALATION OF HIGH CONCENTRATIONS OF OXYGEN FOR TWENTY FOUR HOURS ON NORMAL MEN AT SEA LEVEL AND AT A SIMULATED ALTITUDE OF 18,000 FEET

JULIUS H COMROE JR, M.D.

The effects produced by breathing high concentrations of oxygen for prolonged periods of time have been studied intensively by many investigators in a variety of animals including frogs, turtles, pigeons, mice, rats, guinea pigs, cats, dogs and monkeys.[1] Practically all of these investigators have reported the occurrence of irritation, congestion and edema of the lungs and even death following long exposures. Because of the recent introduction and widespread use of apparatus designed to deliver 100 per cent oxygen it is highly important that similar well controlled experiments be done on man to determine the limits for safe oxygen usage in therapy and in aviation. Satisfactory experiments of this type have not yet been performed. Behnke[2] reported that healthy men between the ages of 20 and 40 are unable to breathe 99 per cent oxygen for periods in excess of seven hours because of nausea, dyspnea and substernal soreness; complete data were not given in his report in respect to the number of subjects, apparatus used, temperature, humidity, carbon dioxide content of inspired gas and other details. In a later report he[3] indicated that some individuals tolerated 99 per cent oxygen for as long as seventeen hours. A more complete investigation was carried out by Becker-Freyseng and Clamann[4] on 2 men breathing 90 per cent oxygen for sixty-five hours. The vital capacity was reduced in both, and 1 developed nausea, repeated vomiting, tachycardia, a febrile tracheobronchitis, dyspnea and pain in the elbows and knees. Neither Behnke nor Becker-Freyseng and Clamann employed controls breathing room air under identical circumstances.

These reports by Behnke and Becker-Freyseng and Clamann are at variance with the clinical opinion of Boothby,[5] who has "employed 100 per cent oxygen continuously for forty-eight hours in more than 800 patients without toxic actions," and of Evans,[6] who has never observed any untoward effects in more than 800 patients receiving 100 per cent oxygen therapy. However, we must point out that patients rarely if ever receive 100 per cent oxygen continuously for several reasons: 1. The mask is usually removed every two to three hours for feeding, drug administration or nursing care. The use of the word continuous by some authors is therefore not justified. 2. The B. L. B. nasal mask[7] may deliver 40 to 95 per cent oxygen, depending on whether the mouth is open (eating, talking, snoring) or closed. 3. The B. L. B. oronasal mask does not necessarily deliver 99 per cent oxygen because it employs partial rebreathing through a reservoir bag and because it permits outside air to be drawn through the sponge rubber disks when the respiratory volume of the subject is in excess of the volume delivered by the oxygen regulator. The same is true of the O. E. M. mask;[8] when demand exceeds the rate of flow the bag is collapsed and air is drawn in through the safety valve. 4. Neither the B. L. B. nor the O. E. M. mask fits the face tightly enough to exclude room air unless special precautions are taken in the fitting of the mask; this is particularly true in individuals with thin bony faces or with edentia. 5. The B. L. B. and O. E. M. oxygen masks may easily be displaced in sleep, and we have repeatedly seen persons (theoretically receiving 100 per cent oxygen) whose masks were on a cheek or the chin during sleep while the mouth or nose was completely uncovered. 6. Masks are often removed deliberately or unconsciously by anoxic patients.

For all these reasons, unless patients are observed by competent investigators continuously for twenty-four or forty-eight hours, with frequent analyses of mask air for percentage of oxygen, these observations[9] cannot be used as arguments against the possible occurrence of oxygen toxicity in man.

We therefore undertook to study with continuous observations a large series of normal men exposed to 98 to 99.5 per cent oxygen for twenty-four hours, with a sufficient number of controls to enable us to state with certainty that oxygen does or does not produce toxic symptoms when so given.

METHODS

Ninety healthy young men between the ages of 19 and 31 years were used; all of these subjects were under continuous observation for twenty-four hours by

From the Department of Pharmacology, University of Pennsylvania Medical School, and Department of Anesthesia, Hospital of the University of Pennsylvania

The work described in this paper was done under a contract, recommended by the Committee on Medical Research, between the Office of Scientific Research and Development and the University of Pennsylvania. Financial support was also received from the National Committee for Mental Hygiene from funds granted by the Committee on Research in Dementia Praecox founded by the Supreme Council, 33° Scottish Rite, Northern Masonic Jurisdiction, U. S. A.

Col C. P. Rhoads and Major Louis Venet, Medical Division, Chemical Warfare Service, furnished much of the apparatus used. Messrs. Dunne and Levin of the Paschall Oxygen Company, Philadelphia, prepared most of the oxygen mixtures used in the experiments. Elizabeth Parcels performed the hematologic studies. Dr. David Drabkin performed the spectrophotometric determinations of total blood pigments. Mr. Herbert Hadley made available civilian public service volunteers. Miss P. Walker rendered valuable technical assistance.

one or more of us. All our experiments were carried out at 1 atmosphere pressure (sea level) unless otherwise noted.

The first six experiments were performed singly. Each of the 6 subjects was placed at complete bed rest in a Heli-Ox hood closed circuit rebreathing apparatus.[10] Carbon dioxide was absorbed completely by baralyme. In addition to other measurements to be discussed later, oxygen and carbon dioxide concentrations, temperature and relative humidity within the hood, and pulse and respiratory rate were recorded at least once every thirty minutes.

In the other eighty-four experiments gas mixtures were administered through a demand system set at 1 inch of water positive pressure on inspiration, employing the Army gas mask with expiratory valve but without the customary canister. This is a full face mask and possesses the advantages of sealing tightly even during sleep, regardless of the shape or contours of the face, and of having a large enough dead space (300 to 400 cc.) to act as an excellent humidifier. Oxygen and carbon dioxide analyses were performed on the Scholander analyzer,[11] using samples withdrawn from the mask during inspiration. The carbon dioxide percentage occasionally exceeded 1 in 49 subjects, 1.5 in 28 and 2 in 5 subjects; 85 per cent of all carbon dioxide determinations in all subjects were less than 1.5 per cent of carbon dioxide, and only 3 per cent exceeded 2 per cent of carbon dioxide. An oxygen distributing line was used so that 20 men could receive the gas mixtures during the same twenty-four hour period. This permitted a large number of controls to be run simultaneously with the subjects receiving high oxygen concentrations. Oxygen was obtained from two different manufacturers; it was prepared by distillation of liquid air and supplied in medicinal cylinders of 240 or 300 cubic feet capacity.

All of these 84 individuals were studied with respect to symptomatology, vital capacity, pulse rate and physical examination of the chest. Complete venous blood studies (red blood cells, white blood cells, hemoglobin, differential, reticulocytes, hematocrit) were performed on 38 of these subjects.

Measurements of relative humidity of mask or hood air were made on representative subjects. No effort was made to provide unusually moist or dry air. The subjects in the hood breathed air with a relative humidity of 44 to 79 per cent (average 68 per cent); the hood temperature was usually 21 C. The relative humidity of the gas breathed by those wearing masks ranged from 38 to 47 per cent (average 40 per cent); this was determined by measuring the temperature of inspired air inside the mask (31 C.) and the dew point of small samples of air withdrawn from the mask during twenty consecutive inspirations. Actually the average amount of moisture contained in the gas breathed by the masked groups (13.1 Gm. of water per cubic meter) was greater than in the hood group (12.3 Gm. of water per cubic meter). Since the alveoli saturate the incoming air with water vapor at 37 C., it is the moisture content in grams of water per cubic meter of gas that determines the drying action. In this instance air with a relative humidity of 40 per cent contained more moisture than air with a relative humidity of 68 per cent; this is due to the fact that the temperature in the former was greater than in the latter. Consequently all the subjects in these experiments were breathing moist gases.

The 84 men wearing masks were permitted to be ambulatory to the extent of their 6 foot hose line. All 90 subjects slept six to twelve hours of the twenty-four. The masks or hood were not removed for feeding, which was accomplished by providing 1,500 to 4,000 cc. of liquid diet (soup, milk, eggnog, fruit juices, coffee, tea, water) via a tube or catheter sealed into the hood or inserted under the gas mask flap and held in place to prevent leakage. Descriptions of symptoms experienced were volunteered by the subjects and never elicited by leading questions. All of the subjects including the controls breathing air were told that they were breathing 100 per cent oxygen regardless of the concentration actually provided.

RESULTS

The data will be discussed from two points of view:

(A) Symptoms produced by inhalation of the gas mixtures and

(B) The effects of high concentrations of oxygen on the blood, circulation and respiration.

A. *Symptoms.*—1. Substernal Distress: Thirty-four subjects (6 in hood and 28 wearing masks) inhaled 100 per cent oxygen[12] continuously for twenty-four hours. The most prominent symptoms during the period was substernal distress. Four of the 6 men in the hood and 24 of 28 subjects wearing masks complained of this discomfort. It was considered slight in 4, of moderate intensity in 18 and severe in 6. It was characterized as a substernal ache which often became sharp and severe during inspiration. The sensations were described as follows: "felt as though I had been smoking excessively," "as though breathing raw, cold air," "as though I had just run a race to the point of exhaustion," "felt like bronchitis." The symptoms were quite similar to those of mild "chokes." The substernal distress was noted at an average time of fourteen hours after the start of the oxygen, the range being from four hours to twenty-two; 79 per cent of those developing substernal distress first noticed this symptom between the twelfth and the sixteenth hour. It was never severe enough to necessitate discontinuance of the experiment before the end of the twenty-four hour period. In some subjects the discomfort diminished as the experiment proceeded, but in the majority signs of greater irritation became evident. In some of the latter the pain increased in severity until it became continuous; in these a deep breath led to coughing or was so uncomfortable as to force the subject to limit his respiratory excursion.

Pain was localized to the right or left of the sternum in a small group, but in the majority of instances it was in the midsternal area. In a few cases the discomfort was centered above the sternal notch "in the throat" or "in the neck." Eight subjects noted aggravation of the discomfort when the mask was removed at the end of the experiment. A similar phenomenon was noted in one instance by Behnke.[3] It is possible that the inhalation of unfiltered, cooler, drier room air containing dust was responsible for this.

12. The mask air contained 0.5 to 1.5 per cent nitrogen or argon and the small amounts of carbon dioxide mentioned. The concentration of oxygen inspired in the experiments conducted in the hood was 98.5 to 99.5 per cent of oxygen; in the experiments employing the masks, it was 97.5 to 99.0 per cent of oxygen. However, for purposes of brevity these individuals will be referred to throughout the paper as the "100 per cent oxygen" group.

An almost universal complaint in the postexperimental period was an accentuation of the substernal distress by deep inspiration, by breathing cold air or by smoking. The symptoms then gradually decreased in intensity over a period of four to five hours, with total disappearance at the end of twelve hours except in 3 men, who had symptoms which persisted for sixteen, twenty-four and thirty-one hours.

An attempt was made to discover whether these symptoms were due to the high tension of oxygen or to adventitious circumstances such as the apparatus used, humidity, resistance to respiration or substances carried over from the tubing or cylinders. To determine this, 10 men breathed compressed room air continuously for twenty-four hours at the same time as 10 of the 28 mentioned before. The oxygen and air cylinders were filled by the same manufacturer and were selected from standard stocks of medicinal oxygen cylinders; the regulators, the copper and rubber tubing, the demand valves and the oxygen masks were identical in the two groups; the relative humidity and carbon dioxide concentrations of the inspired air were the same in the two groups; the groups were observed under the same external environment and with similar fluid intakes, and both groups thought they were breathing 100 per cent oxygen. Nevertheless 9 of the 10 men breathing 100 per cent oxygen developed substernal distress, while none of the 10 breathing air had any corresponding symptoms during the twenty-four hour period. This shows conclusively that the substernal distress was due to inhalation of 100 per cent oxygen.

We then tried to determine the percentage of oxygen required to produce substernal distress. Nine men inhaled 75 per cent oxygen with a fifteen minute intermission every three hours for twenty-four hours and 10 men 50 per cent [13] oxygen continuously for a similar period. Five of the 9 subjects breathing 75 per cent oxygen developed this characteristic symptom, while none of the 10 exposed to 50 per cent oxygen had any complaints referable to the chest. It appears that the concentration of oxygen required to produce symptoms in normal men lies between 50 and 75 per cent and probably is close to the 60 per cent level estimated as safe by Bean [1] and by Stadie.[14]

Since exposure to gas mixtures low in nitrogen results in elimination of nitrogen from alveoli, blood and tissues, it was considered possible that the low tension of nitrogen rather than the increased amount of oxygen might be responsible for the chest pain. Accordingly 6 men were placed in a low pressure chamber at a simulated altitude of 18,000 feet (total pressure of 380 mm. of mercury) and given 100 per cent oxygen through masks. This resulted in a low nitrogen tension and an oxygen tension roughly equivalent to that obtained in the inspired air when breathing 50 per cent oxygen at sea level. None of the 6 subjects developed any substernal discomfort during the twenty-four hour period. It must therefore be concluded that it is the presence of high tensions of oxygen (in excess of 380 mm. or 50 per cent oxygen at sea level) which is required to produce the symptoms mentioned.

It is interesting to note that while none of those breathing 21 per cent or 50 per cent oxygen at sea level or 100 per cent oxygen at 380 mm. had substernal discomfort during the twenty-four hour period, 1, 5 and 2 subjects in these groups respectively had very slight temporary discomfort after the experiment either during the measurement of vital capacity or on going out into cold air. It is possible that prolonged breathing through the rubber tubing or apparatus produced a very mild subclinical irritation.

It has been suggested [15] that intermittent administration of oxygen is less harmful than continuous oxygen therapy. In order to obtain further information on this point we administered 100 per cent oxygen as follows: (*a*) 7 men were given intermissions of one minute every three hours, (*b*) 7 men were given intermissions of five minutes every three hours and (*c*) 7 men were given intermissions of fifteen minutes every three hours. All 21 subjects breathed oxygen for a total of twenty-four hours, i. e. the intermission periods were added to the total time. The masks were removed and room air was breathed during the intermissions. There was no significant difference between any of these groups and those who received oxygen continuously. Of the 7 with one minute intermissions 6 developed substernal distress, of the 7 with five minute intermissions all developed this symptom and of the 7 with fifteen minute intermissions 6 were similarly affected. It is of interest to note that 8 of 30 subjects who breathed 75 or 100 per cent oxygen intermittently noted aggravation of symptoms during the intermission while breathing room air and amelioration when the oxygen inhalation was resumed; 4 subjects with substernal pain were improved in the intermission period and the remainder noted no definite change in symptoms during intermissions.

As far as total incidence of symptoms (mild, moderate or severe) is concerned there appears to be no significant difference between those given 100 per cent oxygen continuously or with intermissions (chart 1). However, if the symptoms are graded according to their intensity (chart 2) those occuring in the group given 100 per cent oxygen with eight rest periods of fifteen minutes each appear to be less severe.

2. Cough, Sore Throat and Nasal Congestion: Forty-three per cent of those breathing 100 per cent oxygen continuously developed nasal congestion or coryza during or shortly after the twenty-four hour experiment; only 10 per cent of those breathing room air developed similar symptoms. Thirty-two per cent of those breathing 100 per cent oxygen developed sore throat and 54 per cent had occasional or repeated cough; 20 per cent of those breathing room air developed sore or dry thoat and none coughed. The development of these symptoms bore no relation to a person's tendency toward upper respiratory tract infection. It is interesting to note that there is not a striking difference between the control group and the 100 per cent oxygen group in respect to throat irritation. The incidence of upper respiratory tract symptoms in the control group breathing room air may be due to inhalation of volatile substances in rubber or to inability to expectorate or blow the nose or to the fact that the experiments were carried out in December and January, when a certain amount of respiratory infection is to be expected.

3. Eye Irritation: Conjunctival irritation occurred in 23 per cent of those breathing 100 per cent oxygen and in 10 per cent of those breathing room air. Part of this may be attributed to the fact that the gas masks

13. The percentage oxygen (mask analyses) varied from 75 to 79 of oxygen and from 49 to 53 of oxygen.

L.; Eckman, M.; Oppenheimer, E. T.; Rumsey, C., Jr., and Soroka, M.: Observations on Methods of Increasing Resistance to Oxygen Poisoning and Studies of Accompanying Physiological Effects, Am. J. Physiol. **142**: 462-475 (Oct.) 1944.

conducts the inspired air directly over the eye pieces; part may be ascribed to the irritancy of oxygen per se. The difference between the two groups is not significant.

4. Lower Respiratory Tract Damage: Since high concentrations of oxygen may irritate the conjunctiva, nose, throat, trachea and bronchi of man and since it is known that they may produce pulmonary congestion and edema in animals, it seemed important to determine whether alveolar damage resulted in man. The distribution of the substernal pain, its aggravation by inhalation of dry, cool ambient air, by cigarets and deep breathing strongly suggest the existence of a tracheobronchitis. In an attempt to determine coexistence of alveolar damage we measured vital capacity before and after the experiment on each subject; three or four determinations were made at each time, and the average of the two highest was recorded. The vital capacity of each of the 10 control subjects breathing room air increased, the average being 210 cc., at the end of the twenty-four hour experimental period (chart 3). This increase is probably attributable to the fact that the original vital capacity was determined on all subjects within thirty minutes after their evening

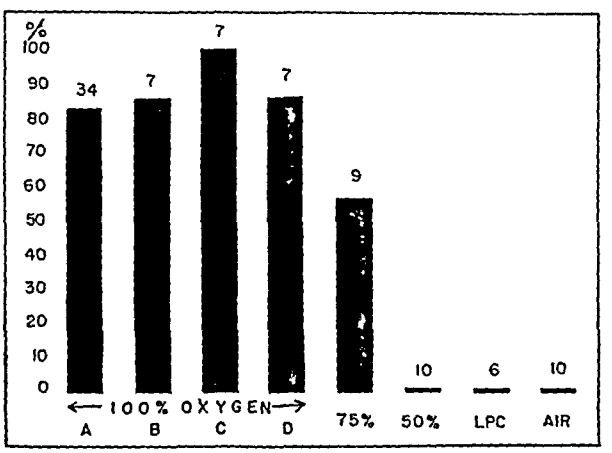

Chart 1.—Incidence of substernal discomfort. Solid bars show the percentage of subjects in each group who developed substernal discomfort during the twenty four hour inhalation. The first four groups inhaled 100 per cent oxygen; of these group A breathed oxygen continuously for twenty four hours, group B had a one minute intermission every three hours, group C five minute intermission every three hours and group D fifteen minute intermission every three hours. *75 %* indicates inhalation of 75 per cent oxygen, 50, 50 per cent oxygen. *LPC* indicates inhalation of 100 per cent oxygen in a low pressure chamber at 18,000 feet. *AIR* indicates inhalation of compressed air. The numbers above each bar indicate the number of subjects in each group.

meal, while the final measurement was made after twenty-four hours of a liquid diet with no intake at all during the last two to three hours. The relatively empty gastrointestinal tract presumably allowed the diaphragm to descend farther and enabled the subject to take a deeper breath or to expel more completely the inspired air.

In contrast to these findings, 63 of the 80 subjects breathing 50, 75 or 100 per cent oxygen showed a decreased vital capacity. In 38 subjects the diminution amounted to more than 200 cc., in 26 to more than 300 cc. and in 15 to more than 400 cc. (the maximal decrease was 1,480 cc. in 2 instances). In view of the data obtained in the group breathing room air it seems fair to assume that the base line for comparison should be plus 200 cc. This accentuates the diminution in vital capacity found in the subjects breathing increased concentrations of oxygen. Furthermore, in those subjects breathing 100 per cent oxygen abdominal distention should have been at a minimum, since Fine and his associates[16] have shown that this procedure leads to absorption of nitrogen from the gastrointestinal tract and a decrease in bowel lumen; this should permit easier descent of the diaphragm and increase the vital capacity. The decreased vital capacity observed

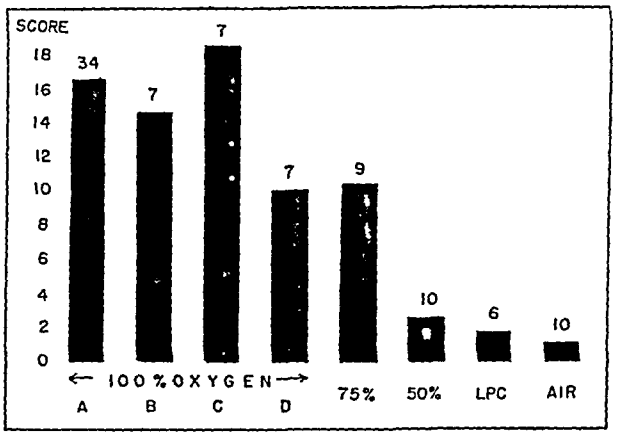

Chart 2.—Severity of substernal discomfort. The groups are the same as in chart 1. Severity of symptoms has been rated as follows: severe discomfort during the experiment 30 points, moderate discomfort 20 points, mild discomfort 10 points, slight temporary discomfort occurring only after the twenty four hour experiment 5 points. The total score in each group was divided by the number of subjects of each group to determine the average severity per subject.

in men breathing higher concentrations of oxygen is therefore significant.

The cause of this reduction in vital capacity is not certain. In some instances the subject was unwilling to make a maximal inspiratory effort because of pain. More often, however, the decrease in vital capacity bore no relationship to the severity of the substernal distress. Thus, of 26 instances in which the vital capacity was decreased more than 300 cc., in only 5

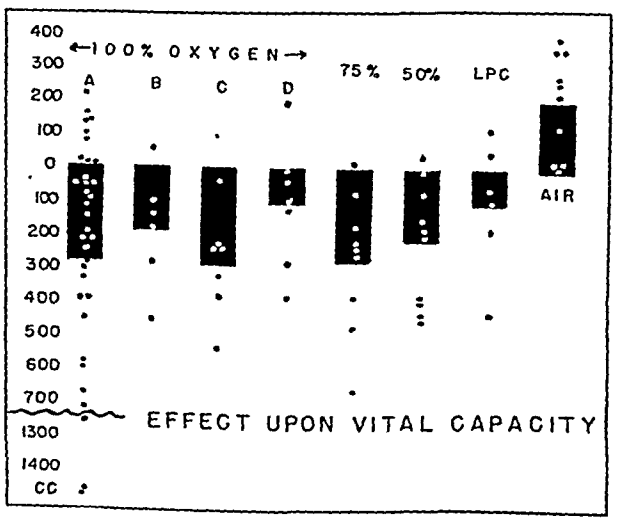

Chart 3.—The groups are the same as in charts 1 and 2. The individual variations in vital capacity from the beginning to the end of the experiment and the average for each group are shown. Above zero represents an increase in vital capacity, below represents a decrease.

was the substernal distress severe, in 9 it was moderate, in 4 slight and in 8 lacking entirely. Among 15 subjects in whom the vital capacity was decreased more

16 Fine, J.; Hermanson, L., and Frehling, S.: Further Clinical Experiences with 95 per Cent Oxygen for the Absorption of Air from the Body Tissues, Ann. Surg. **107**: 1-13 (Jan.) 1938.

than 400 cc., only 4 had severe distress, 5 had moderate discomfort, 2 slight and 4 none at all. Conversely, of the 26 subjects who had no substernal distress during inhalation of 50 to 100 per cent oxygen 7 had a decrease in vital capacity of more than 380 cc.

Since the decreased vital capacity could not be correlated positively with substernal distress, other explanations must be sought. Atelectasis (due to absorption of oxygen from poorly ventilated alveoli), pulmonary congestion (caused by the irritant effect of oxygen) or early pulmonary edema were considered. X-rays of the chest were taken in 6 subjects before and after the twenty-four hour exposure; these revealed no abnormalities, but it is likely that roentgenograms would not detect minor changes in the lungs. Physical examination of the chest was performed in all 90 subjects and likewise failed to reveal any pulmonary abnormalities after the twenty-four hour period. The arterial oxygen saturation (6 subjects) showed no significant changes during or immediately after the twenty-four hour period and direct measurements of arterial oxygen tension[17] in 2 subjects showed no deviation from normal at the end of twenty-four hours. This indicates that the ability of the alveolar membrane to transport oxygen was not interfered with. The minute volume of respiration was measured in 6 subjects breathing room air before and immediately after the twenty-four hour exposure to 100 per cent oxygen in the hood. It was increased after the experiment in only 2 of the 6; 1 of these had a 13 per cent increase in minute volume and a 33 per cent increase in rate, and the other had a 25 per cent increase in minute volume and a 20 per cent increase in rate. The former had very severe symptoms and a decreased vital capacity of 1,480 cc.; the latter had neither. Since pronounced changes in vital capacity must occur before minute volume is definitely increased,[18] respiratory changes are not sensitive indicators of pulmonary atelectasis, congestion or edema.

In summary, the only evidence of alveolar damage obtained in these experiments was a decrease in vital capacity occurring in subjects who had no substernal pain or cough. In view of alveolar damage that occurs in animals with longer exposure to 100 per cent oxygen, we believe that these subjects had signs of early pulmonary irritation.

5. Other Symptoms: Twenty-five per cent of those inhaling 100 per cent oxygen continuously developed ear discomfort during or (usually) after the experiment. Only 5 per cent of those breathing 100 per cent oxygen intermittently and 10 per cent of those breathing room air developed this symptom. It was due probably to absorption of gas from the middle ear (aural atelectasis); this occurs more rapidly when the gas breathed is 100 per cent oxygen. Since such gas is absorbed only when the pharyngeal end of the eustachian tube is closed, this indicates that a mild inflammatory reaction must have occurred in the nasopharynx.

Unusual degrees of fatigue were reported by 25 per cent of those breathing 100 per cent oxygen continuously and by 10 per cent of those breathing room air. Five subjects noted joint pains or crackling in the joints during or after the breathing of 100 per cent oxygen for twenty-four hours; these complaints were similar to early signs of bends. Three subjects noted paresthesias such as tingling in the extremities while breathing 100 per cent oxygen; these symptoms were similar to those commonly noted in decompression sickness. Muscle pains in the legs were noted by 4 subjects, hoarseness by 2, palpitation (on exercise) by 3, aching or sensitive teeth by 7, dizziness or lightheadedness in the postexperimental period by 7. None of these symptoms occurred in subjects breathing room air.

B. *Effects of High Concentrations of Oxygen on Other Body Systems.*—1. Red Blood Cells: Red blood cells were counted before and after inhalation of 100 per cent oxygen for twenty to twenty-four hours by 28 subjects and before and after inhalation of room air by 10 subjects. All of the blood studies were carried out on venous blood samples. Duplicate analyses were made. The preexperiment bloods were drawn between 6 and 7 p. m. (after the evening meal); the second sample was taken while the subject was still breathing gas between the twentieth and twenty-fourth hours of the experiment. In the group of 28 breathing 100 per cent oxygen, 19 showed increases in red blood cells ranging from 60,000 cells per cubic millimeter to 1,210,000, and 9 showed a decrease ranging from 40,000 to 640,000; the average for the whole group was an increase of 220,000 cells per cubic millimeter, which is within the limit of error of the method. Of the 10 control subjects breathing room air, 8 showed increases (180,000 to 1,350,000) and 2 showed decreases (80,000 and 540,000); the average for the 10 subjects was an increase of 560,000 cells per cubic millimeter. The increase in red blood cells occurring in the group breathing room air negates any significance which might be attached to the slight rise in red blood cells following 100 per cent oxygen inhalation. Reticulocyte counts were performed on 28 subjects breathing 100 per cent oxygen and in 10 controls breathing room air. In only 3 of the 28 did the count rise above 1.0 per cent (1.2, 1.8, 2.8 per cent); in 2 of the controls it rose above 1.0 per cent (1.5 and 4.0 per cent).

2. Hemoglobin: Hemoglobin was converted into cyanmethemoglobin and measured as total pigment by the Evelyn photoelectric colorimeter using constants obtained by comparison with the spectrophotometric method of Drabkin.[19] Of 28 subjects breathing 100 per cent oxygen, in 12 an increase occurred (0.15 Gm. to 0.89 Gm.) and in 15 a decrease occurred (0.13 Gm. to 1.67 Gm.); in 1 there was no change. The average of all 28 showed a decrease of 0.13 Gm. Of the 10 controls breathing room air, in 6 the hemoglobin increased (0.13 to 0.78) and in 4 it decreased (0.06 to 0.85); the average was an increase of 0.11 Gm. These average changes are not significant. It is interesting to note that hemoglobin determinations (done by a very accurate method) may vary by almost 1 Gm. on two successive days even though breathing room air. This confirms the observations of Dreyer and his associates[20] and of Rabinowitch.[21]

3. Hematocrit: Hematocrit determinations were done on 27 subjects breathing 100 per cent oxygen; 16 showed an increase (0.2 to 4.6 per cent), 10 showed a decrease (0.1 to 3.6 per cent) and 1 showed no change. The average change was an increase of 0.36

per cent. Similar determinations were performed on the subjects breathing room air; 5 increased (0.6 to 4.8 per cent) and 5 decreased (0.2 to 1.9 per cent). The average was an increase of 0.55 per cent.

4. White Blood Cells: Of the group of 28 breathing 100 per cent oxygen, the white blood cells count did not change in 3, increased in 7 (by 100 to 6,100 cells per cubic millimeter) and decreased in 18 (by 100 to 3,200 cells per cubic millimeter). The average change was a decrease of 190 cells per cubic millimeter. The apparent decrease in white blood cells postexperimentally was probably due to the fact that the control blood was obtained one hour after the evening meal and the white blood cells were slightly elevated at this time in response to food. This explanation is strengthened by the fact that in the group of 10 controls breathing room air the white blood cells decreased in 7 (by 50 to 2,900 cells per cubic millimeter) and increased in only 3 (100 to 3,500); the average decrease was 440 cells per cubic millimeter. The highest absolute level to which the white blood cells rose in the group breathing 100 per cent oxygen was 12,400 in 1 case (this subject had only slight substernal discomfort); in only 2 other instances did the white blood cells rise over 10,000 (10,350 to 10,100). The leukocytosis described by Behnke [2] and Becker-Freyseng and Clamann [4] was therefore not observed in this series. No abnormalities were noted in the differential white blood cells (granulocytes, filament and nonfilament, lymphocytes, monocytes, eosinophils or basophils).

In summary, it is apparent that inhalation of high concentrations of oxygen for twenty-four hours does not affect the formed elements of the blood.

5. Arterial p_H and Carbon Dioxide: In two subjects, arterial blood p_H was measured in a closed glass electrode at 38 C. before and at the conclusion of the twenty-four hour period of 100 per cent oxygen inhalation. In neither instance was there a change in p_H greater than 0.01 unit (limit of error of the measurement). Arterial carbon dioxide tension was calculated from measurements of arterial blood p_H and carbon dioxide content; in 1 there was a decrease of 0.7 mm. of mercury and in the other an increase of 1.0 mm. of mercury. Arterial whole blood carbon dioxide content was measured before and at the end of the twenty-four hour period of oxygen inhalation in 6 subjects; in 2 there was no change, in 1 an increase and in 3 a decrease; the average change was a decrease of 1.03 volumes per cent.

6. Pulse: A slowing of the pulse has been reported [22] during the inhalation of 100 per cent oxygen. This has been confirmed in this study, but since the control subjects breathing room air showed a bradycardia to the same degree it is obvious that this pulse slowing represents the effect of bed rest rather than of the gas breathed (table 1).

The figures in the last two columns were obtained as follows: At the end of the experiment the subjects were put at complete rest for fifteen to forty-five minutes while still breathing the gas and a pulse count was taken; then the mask was removed and the subject continued resting for another fifteen to forty-five minutes and the second count (room air) taken. In no case was there any significant increase in pulse on changing from oxygen to room air.

7. Blood Pressure: In 28 subjects breathing 100 per cent oxygen and in 10 breathing room air the blood pressure was determined before the experiment (twenty minutes' rest), at the end of the twenty-four hour period (twenty minutes' rest) and twenty minutes after removal of the mask. The average figures are shown in table 2. These figures show no significant trend in blood pressure as a result of inhalation of 100 per cent oxygen.

8. Respiration: In the 84 subjects wearing masks respiration was not measured quantitatively, but there was no instance in which dyspnea or hyperpnea was noted by subjects or observers. The total number of liters of oxygen used per subject in twenty-four hours could not be measured accurately because of wastage during tube feeding but corresponded roughly with the calculated amount for subjects at partial rest. In the 6 subjects in the hood, the respiratory rate was counted at least twice an hour for the twenty-four hours. In no instance did the respiratory rate increase above normal figures during the period of oxygen inhalation. These findings do not controvert previous findings [23] that oxygen increases respiratory minute volume by 10 to 15 per cent, for the experimental conditions in this work do not compare with the former; however, the break in respiratory compensation and dyspnea seen by others [2] did not occur in our experiments.

TABLE 1.—*Effect of 100 per Cent Oxygen on Pulse as Compared with Controls*

	Before Experiment	Lowest During Experiment	End of Experiment, 15' Rest	After Experiment, 30-40' Rest
100% oxygen				
Hood (average 6 men).....	69	49	61.6	60.6
Mask (average 28 men).....	80.5	55.5	65.6	67.3
Room air				
Mask (average 10 men).....	80.6	56 2	63 6	67.2

TABLE 2.—*Effect of 100 per Cent Oxygen on Blood Pressure as Compared with Controls*

	Before Experiment	End of Experiment	After Experiment
100% oxygen (28 men).....	128/76	127/75	122/76
Room air (10 men).....	126/78	120/76	119/80

COMMENT

There is no agreement whatever among clinical investigators concerning the harmful effects of oxygen on man. At one extreme Behnke has reported that healthy men between the ages of 20 and 40 are not able to breathe 99 per cent oxygen for periods in excess of seven hours, dyspnea, flushing of the face, nausea and substernal soreness terminating his experiments. At the other extreme are statements that 100 per cent oxygen is harmless in man when breathed continuously for forty-eight hours (Boothby) or even for much longer periods (Evans). Our results do not agree with either of these views. We have shown that signs of respiratory irritation do occur in man, characterized chiefly by substernal soreness. The average time of onset was not seven hours but fourteen hours, and all of the subjects were able to tolerate this discomfort for the full twenty-four hour period. As is the case with animals, there appears to be a factor of individual variation, some subjects having severe symptoms and a few

none at all. We have no explanation for the dyspnea, flushing and nausea noted by Behnke; these symptoms did not occur in our series. However, we can offer an explanation for the failure of other observers to note toxic effects from oxygen inhalation in man. As indicated previously, so-called "100 per cent" oxygen as administered clinically rarely approaches that concentration. The data of Reinhard and his associates [24] illustrate this very well. They report the administration of 70 to 100 per cent oxygen "continuously" for eight to twenty days to 4 patients with sickle cell anemia. However, while oxygen was administered for a total of seventy-two patient days, alveolar oxygen concentrations were determined only four times over this whole period (three times in 1 patient, once in another and not at all in 2 patients). Since these four analyses varied from 63.4 to 90.6 per cent oxygen, it is obvious that some might have been considerably lower, especially during sleep. It is impossible to tell whether these patients were breathing 60 to 70 per cent oxygen or 80 to 90 per cent oxygen and, since 60 per cent oxygen produces no toxic symptoms but 75 per cent may, no conclusions can be drawn from such uncontrolled observations. Their arterial blood analyses also suggest that less than 60 per cent oxygen was being inhaled, since inhalation of 100 per cent oxygen should result in at least 1.5 cc. of additional oxygen carried in the plasma over that dissolved when blood is equilibrated with room air; yet an increase in excess of 0.4 cc. was not recorded in their series. We began our investigation using several half-face masks (aviation type) and found that these often provided only 50 per cent oxygen. Clinicians must recognize the fact that just as oxygen tents leak and often provide only 30 per cent oxygen instead of 60 per cent, so masks will also leak when improperly applied. Figures relating to concentrations of inhaled oxygen are meaningless unless frequent determinations of oxygen concentrations in the mask are performed around the clock (during the patient's sleeping as well as his waking hours).

Another explanation for the failure of clinicians to observe the toxic effects of high oxygen concentrations is that patients with pneumonia or coronary occlusion may be so uncomfortable as a result of the pain of pleurisy or of cardiac ischemia that the substernal discomfort produced by oxygen may be overlooked.

Since we have shown that it is possible to provide patients with 100 per cent oxygen continuously by the use of full face mask and demand apparatus, and since such apparatus may soon be made available for clinical use, it becomes necessary to consider the advisability of this procedure. We feel that the clinician must bear in mind that oxygen is a drug and must be used in accordance with well recognized pharmacologic principles; i. e., since it has certain toxic effects and is not completely harmless (as widely believed in clinical circles) it should be given only in the lowest dosage or concentration required by the particular patient. Our results indicate that the instance of oxygen toxicity reported by Becker-Freyseng and Clamann [4] was not a chance observation and did not represent individual susceptibility but was an example of a now well defined clinical entity characterized by rhinitis, pharyngitis, substernal pain accentuated on deep breathing and pulmonary change manifested by a decreased vital capacity. Over a twenty-four hour period this pulmonary change probably is not extensive enough to result in any loss of lung function (such as proper oxygenation of the blood). While prolongation of the period of oxygen breathing to two, three or four days was not feasible in our experiments, we must assume on the basis of these twenty-four hour experiments, of Becker-Freyseng and Clamann's sixty-five hour experiments and of animal experiments, that severe pulmonary congestion and edema can result in man breathing oxygen for a sufficient period of time. In our experience the symptoms were never alarming and were rapidly reversible on cessation of the oxygen inhalation with no permanent harm resulting. This may not be true of longer exposures in normal men or even of short exposures in persons with pulmonary disease.

While we know that the tolerance of normal men to inhalation of 100 per cent oxygen continuously is in excess of twenty-four hours, we have little accurate information regarding the time required to produce pulmonary changes in lungs already damaged by inflammation or by irritant gases (industrial or war gases); we excluded from our tests all persons with rhinitis, pharyngitis or bronchitis. Until we are proved to be wrong, we think it is reasonable to assume that 100 per cent oxygen would be even more irritant when placed in contact with surfaces already damaged.

These are several dissenting points of view: (*a*) Evans [6] believes that inhalation of 100 per cent oxygen cannot be harmful to a patient with arterial anoxemia, for 100 per cent oxygen in such a case never raises the oxygen pressure to the toxic level which might be obtained in normal men. This is due to the presence of pulmonary transudate or exudate (as in pulmonary edema or bronchopneumonia), which prevents the high tension of oxygen from reaching the alveolar membrane. However, only the damaged alveoli would be thus protected from the harmful effects of high oxygen, which could still be exerted on the remaining normal alveoli or on the tracheobronchial tree. (*b*) Drinker [25] believes that the use of 100 per cent oxygen can actually aid in the resorption of pulmonary transudates. However, this is true only when the pulmonary edema is due primarily to severe anoxia with resultant increase in capillary permeability; in such instances 100 per cent oxygen would tend to reverse this process at least initially. The great majority of pulmonary transudates are not caused primarily by anoxia.

In general it may be said that there are three chief groups of indications for oxygen therapy: (1) to combat arterial anoxemia, (2) to hyperoxygenate the blood in conditions not associated with anoxemia (coronary occlusion, fever, migraine, polycythemia and so on) and (3) to eliminate nitrogen from the body (to prevent decompression sickness or to combat intestinal distention).

With respect to the first, we believe that the rational use of oxygen in anoxemic states should be governed by measurements of arterial blood oxygen saturation. The technics of arterial puncture and determination of arterial blood oxygen saturation by the Van Slyke method are simple enough to be employed more widely. It is amazing that, in an era when sulfonamide, penicillin, quinacrine (atabrine) and other types of therapy are being made more exact by studies of drug concentration in the blood, blood oxygen concentration studies are almost completely neglected in the clinic. The indication for this type of oxygen therapy is decreased saturation of the arterial blood; a high enough dose

24. Reinhard, E. H.; Moore, C. V.; Dubach, R., and Wade, L.: Depressant Effects of High Concentrations of Inspired Oxygen on Erythrocytogenesis, J. Clin. Investigation 23: 682-699 (Sept.) 1944.

25. Drinker, C. K.: Application of Pulmonary Physiology to Theoretical Procedures, New England J. Med. 231: 477-482 (Oct. 5) 1944.

or concentration has been given when the oxygen saturation has returned to normal, and it is not necessary to exceed this. We believe that 100 per cent oxygen may be given with safety to all anoxemic patients for short periods. When oxygen therapy must be continued beyond a twelve hour period, the concentration should be decreased to 50 or 60 per cent unless this is insufficient properly to oxygenate the arterial blood. When unsaturation of the arterial blood persists despite inhalation of 60 per cent oxygen, 80 to 100 per cent oxygen should be given, since arterial unsaturation represents more of a threat to the patient's life than does the possibility of a tracheobronchitis due to the oxygen. We take the conservative stand that 100 per cent oxygen should be used for long periods only when lower concentrations fail to saturate the blood. Many patients given oxygen therapy are seriously ill and ultimately die; it is difficult to assess the harmful effects of oxygen in these cases [26] and at present we must transfer to the therapy of these individuals knowledge gained in dealing with normal subjects. Physicians must not construe these statements to mean that oxygen therapy in general is harmful; oxygen therapy is of great value with practically no harmful effects when used in scientifically controlled concentrations.

With respect to the second indication for 100 per cent oxygen therapy (hyperoxygenation of the blood in conditions not associated with anoxemia or lung damage) it appears safe to use 100 per cent oxygen for twenty-four hours and possibly longer, for these individuals are wholly comparable to our normal subjects. In these cases the physician should question the patient every six hours in regard to substernal distress, especially following deep breathing or removal of the mask; if not contraindicated clinically, a careful vital capacity determination should be made twice daily to detect the appearance of pulmonary congestion.

With respect to the third group (denitrogenation) there is rarely a need for prolonged breathing of 100 per cent oxygen since nitrogen is eliminated from the body within several hours. Further inhalation of 100 per cent oxygen to remove nitrogen and relieve intestinal distention should not be necessary unless the patient swallows air on removal of the mask; in our opinion other procedures, such as intubation with the Miller-Abbott tube, should be tried first before resorting to prolonged breathing of 100 per cent oxygen.

With respect to the causation of the symptoms of oxygen toxicity, we have shown for the first time in man that these symptoms are caused by the high tension of oxygen rather than by denitrogenation. Our experiments with 100 per cent oxygen at an ambient pressure of 380 mm. of mercury show that denitrogenation per se does not produce symptoms as long as the oxygen tension is not abnormally high. This indicates that prolonged inhalation of 100 per cent oxygen at high altitudes in aircraft will not be harmful because the total atmospheric pressure is so low that even though all the gas inspired is pure oxygen its total pressure will never reach the irritant level. This confirms the opinion formed by Armstrong [27] on the basis of animal experimentation.

Our experiments have not confirmed the work of those investigators who have reported significant changes in hemoglobin, red blood cells, white blood cells, reticulocyte counts, pulse or blood pressure as a result of inhalation of oxygen for long periods. We believe that those who have previously reported these changes were misled because of lack of proper controls or by the use of blood obtained by finger puncture. We found no significant change in arterial blood p_H, carbon dioxide content or carbon dioxide tension at the end of twenty-four hours oxygen inhalation; we did not obtain mixed venous blood for p_H or carbon dioxide tension determinations.

One might wonder why the inhalation of 100 per cent oxygen affects chiefly the respiratory tract. We believe this is because these are the only surfaces in the body that are exposed to 100 per cent oxygen or a pO_2 of 670 to 690 mm.; despite the high arterial blood pO_2, the average tissue tension elsewhere is probably not over 70 mm. of mercury because of the steep pO_2 gradient in the capillaries. The pulmonary membranes, on the other hand, receive the high pO_2 by direct contact with the inspired gas.

We have found that most of the masks in common use do not deliver 95 to 100 per cent oxygen as applied routinely (without special precautions or specially trained attendants). We have found that the full face mask is more suitable for prolonged administration of 100 per cent oxygen. It is easy to apply and remove, is less annoying to the patient, is a good humidifier, fits practically all types of faces, does not build up excessive concentrations of carbon dioxide and may be used with positive pressure breathing if desired. Whenever the use of 100 per cent oxygen is essential for long periods, we recommend the use of this type mask. In view of the experiments of Hulpieu and Cole [28] it seems advisable to use a humidifying system in all types of oxygen administration.

SUMMARY AND CONCLUSIONS

1. One hundred per cent oxygen administered to a large group of normal men continuously for twenty-four hours produced substernal distress in 82 per cent. Vital capacity was usually decreased significantly. Signs of nose and throat irritation were common. Control subjects breathing room air through the same apparatus did not experience these symptoms.

2. Intermittence (up to fifteen minutes rest every three hours) did not decrease the incidence of the complaints.

3. Seventy-five per cent oxygen produced symptoms in only 55 per cent of the subjects; 50 per cent oxygen produced no symptoms during the twenty-four hour period. Since oxygen tents or catheters rarely produce alveolar oxygen concentrations higher than 50 per cent, these forms of administering oxygen are completely safe.

4. Breathing of 100 per cent oxygen at high altitudes (low total atmospheric pressures) does not produce symptoms, indicating that the symptoms are due to high oxygen tensions and not to elimination of nitrogen.

5. The use of 100 per cent oxygen for short periods is probably safe in all patients, but when oxygen must be given in excess of twelve hours the following rules should be followed: (*a*) the oxygen concentration should be reduced to 60 per cent unless this is insufficient to saturate the arterial blood, and (*b*) if 100 per cent oxygen must be administered a careful check should be made for the symptoms most likely to occur as a result of the high tension of oxygen.

THE CLINICAL MANIFESTATIONS OF POLIOMYELITIS

TREATMENT WITH NEOSTIGMINE AND THE KENNY METHOD

HENRY BRAINERD, M.D.
HILLIARD J. KATZ, M.D.
ALBERT PORTER ROWE JR., M.D.
AND
J. C. GEIGER, M.D.
SAN FRANCISCO

During recent years much controversy has centered around the introduction of the Kenny [1] concept of poliomyelitis, which forms the rationale for the treatment which she advocates for the manifestations of this disease. Kenny describes three cardinal symptoms of poliomyelitis: muscle spasm, mental alienation and incoordination. She considers muscle spasm an early and important manifestation of the disease, present in all cases and underlying most of the disability associated with the disease. Mental alienation she describes as the mode whereby the function of a muscle opposed to a muscle in spasm is disturbed although no organic lesion exists in the motor pathways to the muscle. Rather the muscle is dissociated from, or "forgotten" by, the central nervous system. This she considers a more important cause of disability than paralysis due to destruction of motor cells in the anterior horn. Finally, Kenny describes incoordination as the dysrhythmic or inefficient contraction of muscles.

Recent investigation casts doubt on the validity of Kenny's concept. Moldaver [2] found that neuromuscular degeneration was present in all muscles considered "alienated." He felt that muscle spasm was a complex phenomenon produced by three factors: meningeal irritation, enhanced stretch reflexes of muscles opposed to muscles exhibiting neuromuscular degeneration, and irritative lesions of posterior ganglions and posterior horn cells. Schwartz and Bouman [3] were able to demonstrate action currents suggesting spasm in all muscles except those completely paralyzed. Clinical spasm was often not apparent, especially in weak muscles. Likewise, Watkins, Brazier and Schwab [4] found increased action potentials in the resting state in all muscles involved, whether in spasm or weak, especially after three months' recovery period. These observers felt that this was evidence of recovery of innervation. In addition they noted simultaneous action currents to both of two opposing muscles in patients recovering from poliomyelitis, negating Sherrington's law of reciprocal innervation and possibly accounting for the incoordination described by Kenny.

Numerous investigators [5] have reported on the treatment of these manifestations by the Kenny method of hot foments and muscle reeducation, for the most part favorably. Kabat and Knapp [6] first described the use of neostigmine as a method of relaxing muscle spasm when used as an adjunct to hot foments and felt that return of motor power was enhanced and incoordination lessened.

It is our purpose in this paper to analyze the incidence and importance of the various manifestations of poliomyelitis on a purely clinical basis and to attempt to estimate the efficacy of neostigmine and hot foments combined with muscle reeducation in the relief of these phenomena.

CLINICAL MANIFESTATIONS

One hundred cases of poliomyelitis were observed in the Isolation Division of the San Francisco Hospital. These were all acute cases, the duration of illness on entry varying between one and thirty days. The treatment described was usually initiated within the first few days of hospitalization. Sixty-four males and thirty-six females, whose average age was 13.4 years, ranging in age from 3 months to 44 years, were studied.

Muscle Spasm.—All cases exhibited the phenomenon described by Kenny [1] as muscle spasm. This consisted primarily in a hyperirritable stretch reflex producing limitation of movement of parts. In addition, shortening of muscles at rest was often seen producing deformity. That this phenomenon of itself may produce disability is undoubted regardless of its role in production of muscle weakness, as evidenced by the shortened, fibrosed muscles seen in late or neglected cases. The muscles most commonly involved (table 1) were the posterior cervical, back and hamstring groups. These are the groups whose irritability to stretch stimulation is commonly attributed to meningeal irritation. That such is not the case in poliomyelitis is suggested by the persistence of these signs in some cases for many months after all possibility of meningeal irritation is passed, and also by the entire absence of spinal fluid abnormalities in a significant number of patients. In 93 early cases in which lumbar puncture was done, completely negative findings, usually on repeated taps, were obtained in 19, or 20.4 per cent. Seven of these cases showed muscle paralysis. In addition, 4 cases exhibited elevation of spinal fluid protein without pleocytosis. That the spasm was due primarily to enhanced stretch reflexes of muscles opposing muscles undergoing neuromuscular degeneration seemed doubtful, since the muscles opposing the muscles in spasm very frequently gave no clinical evidence of weakness, although no measurements of chronaxia were made.

Muscle Weakness.—This was observed in 48 (48.0 per cent) cases. It frequently existed in muscles whose opponents were not in spasm. However, more commonly the muscle opposing the weak muscle evidenced some degree of spasm. Quite commonly seen was the combination of spasm and weakness in a single muscle, whether or not opposed to a muscle in spasm. These weak muscles often developed atrophy while under treatment. The associated tendon reflexes were depressed or absent in 34.7 per cent of all cases. Hyperactive reflexes were seen in 17.9 per cent of cases, usually when the effector muscle exhibited spasm. Motor power generally returned gradually to weak

The neostigmine used in this study was furnished by Hoffmann LaRoche, Inc.
Mrs. Karen Blake, Miss Norah Lane, Mrs. Carolyn Herndon and the house staff of the San Francisco Hospital rendered invaluable aid in the treatment of these patients.

muscles during reeducation, although rarely almost instantaneous return of function was noted when spasm was relieved and reeducation attempted, suggesting absence of organic interruption of motor pathways.

Incoordination.—We likewise frequently observed incoordination. The most striking example of this misuse of muscles was repeatedly demonstrated in patients having weak quadriceps, who, on being asked to extend the knee, would visibly and palpably contract the hamstrings. This was exhibited less strikingly in other muscles.

TREATMENT

We attempted to study the effects of neostigmine and packs on muscle spasm in two ways. Realizing the tremendous variation in spontaneous recovery rate in poliomyelitis regardless of treatment, we first determined the ability of neostigmine to relax muscle spasm and increase motor power one hour after a hypodermic injection of neostigmine methylsulfate, control measurements having been made immediately before injection. Children under 6 years received 0.5 mg., those between 6 and 12 years 1.0 mg. and adults 1.5 mg. accompanied by 0.4 mg. and 0.6 mg. of atropine in the latter two age groups, as described by Kabat and Knapp.[6] Measurements of range of motion were made with a goniometer. Motor power was estimated only by clinical examination. From repeated measurements of patients under treatment we found that a small variation of less than 10 degrees in either direction in motion occurred frequently, so accordingly we did not consider relaxation significant in the one hour test unless it equaled or exceeded 10 degrees in at least one of the measured movements. Of 28 early cases in which the one hour test was done, 24 (85.7 per cent) showed a significant degree of muscle relaxation within one hour. In individual cases there was often a startling difference in amount of relaxation of various muscle groups, some showing definite improvement and others changing little or not at all. A large number of cases showed a partial or, rarely, complete regression to previous range of motion in spite of continued treatment with packs and neostigmine, with subsequent more gradual improvement. That this was not entirely due to progressive involvement by the disease was suggested by the fact that regression was also observed in some cases first tested over two weeks after onset. Occasionally the relaxation of spasm was dramatic, and in 1 instance of a patient exhibiting moderate spasm of the posterior neck, back and hamstring groups almost complete motion was restored in one hour. In 2 instances of quadriceps muscles exhibiting motor weakness, definite return of motor power was noted during the test period.

Secondly, an attempt was made to compare the effectiveness of neostigmine or hot foments singly or in combination in a selected group of cases without paralysis and having spasm largely limited to the posterior cervical, back and hamstring groups. Thirty-one such cases were studied. Neostigmine was administered subcutaneously every other day in similar dosage to that used in the one hour test. In addition most patients also received neostigmine bromide by mouth thrice daily. Children under 6 years received 15 mg. three times daily, those from 6 to 12 years received 30 mg. thrice daily and adults received 45 mg. on a similar schedule. When parasympathomimetic side effects such as nausea, diarrhea or urgency occurred, increased atropinization almost always promptly relieved them. No serious toxic effects of neostigmine were noted. Measurements of range of motion were made at frequent intervals and comparison was made of the average duration of treatment before complete recovery. The results (table 2) we feel are misleading and illustrate the fact that no statement should be made on the long term results of any treatment of poliomyelitis without a very large controlled series. We suggest a cooperative clinical group for this purpose in the future.

With the exception of 2 patients who had prompt improvement in motor power during the one hour test, muscle power exhibited extreme variation in rate of return. In all, 45 patients were treated with neostigmine. Except in 4 instances these patients also received hot foments. The variation in duration of hospital stay and amount of residual impairment in those receiving packs alone or combined with neostigmine was maximal and would allow no accurate estimation of the relative efficacy of the two modes of treatment.

Certain statements may be made, however, concerning end results of the Kenny treatment with and without neostigmine. Thirty one (31 per cent) of our series have residual muscle weakness. (Two have facial weakness only.) Of this group only 1 has a contracture, not the fault of therapy but due to lack of cooperation. All patients are able to use what muscle power remains with remarkable efficiency. All are able to walk without braces. Fourteen of this group were treated with packs alone, 17 with packs and neostigmine.

TABLE 1.—*Distribution of Muscle Spasm in 100 Patients*

Muscle group	Patients with Spasm, %
Posterior cervical	99.0
Back	100.0
Hamstring	85.0
Quadriceps femoris	30.0
Adductor magnus	28.0
Calf	13.0
Pectoral	9.0
Other	21.0

TABLE 2.—*Treatment of Selected Patients, Exhibiting Only Spasm of Neck, Back and Hamstring Groups*

Treatment	Number of Patients	Average Days Before Recovery	Range of Days Before Recovery
Packs only	17	35.6	10 to 77
Neostigmine only	4	21.8	9 to 36
Packs and neostigmine	10	54.7	7 to 110

CONCLUSIONS

1. Muscle spasm is of uniform occurrence in early poliomyelitis and is of great diagnostic value.
2. Muscle spasm does not appear to be due primarily to meningeal irritation. Spinal fluid pleocytosis is frequently absent.
3. Muscle spasm is in itself disabling, but its role in the etiology of muscle weakness is unproved.
4. Neostigmine methylsulfate will relax the muscle spasm of poliomyelitis at least temporarily.
5. The value of continued medication with neostigmine, orally or subcutaneously, requires further proof, but its further trial under controlled circumstances is definitely warranted.
6. The Kenny treatment with or without neostigmine is an effective method of preventing contracture and deformity.
7. Our study gave no proof nor disproof that either neostigmine or Kenny packs reduce the incidence of paralysis.

San Francisco Hospital, Isolation Division.

THE VALUE OF NEOSTIGMINE IN ACUTE ANTERIOR POLIOMYELITIS

M. J. FOX, M.D.
AND
W. H. SPANKUS, M.D.
MILWAUKEE

Recent developments in the therapy of poliomyelitis have emphasized the element of spasm of the involved muscles and the desirability of treating this spasticity. In the Kenny method, hot foments are used for this purpose. Kabat and Knapp [1] have reported favorably on the use of neostigmine to control the muscle spasm. They have attacked the problem from the point of view of the disturbed neurophysiology described by Watkins, Brazier and Schwab [2] and by Moldaver.[3]

Since many of the patients studied by Kabat and Knapp were in the chronic stage of poliomyelitis, we have been interested in studying the relaxing effect of neostigmine on the acute stage of the disease. Thus far we have used neostigmine in 24 cases in which the age ranged from 3 to 55 years. The patients had been ill with poliomyelitis for an average of only 5.5 days, with the duratioin of the disease before admission to the hospital ranging from one to twenty-one days. The average duration of neostigmine therapy for this group was 14.6 days, while the control cases were studied for an average of 10.8 days.

PROCEDURE

On admission to the hospital all patients were examined thoroughly, spinal taps were performed, and the diagnosis of acute anterior poliomyelitis was thus confirmed. The muscles most commonly found to be in spasm were the gluteals, hamstrings, extensors of the neck and the sacrospinalis groups, but only the hamstring and gluteal muscles have been studied in relation to relaxation in this series.

In order to evaluate the effectiveness of therapy, specific measurements were made of the amount of spasm in these muscles. The degree of spasm in the hamstring muscles was determined by measuring the angle formed at the popliteal fossa between the leg and the thigh, with the thigh flexed at a right angle to the plane of the body. The amount of gluteal spasm was determined by measuring, with the knee extended, the angle formed between the thigh and the support on which the body rested. The patient's subjective sensation of pain was used as the limit of the range of passive motion possible in the affected muscle.

After the admission work-up of the patient was completed, the following regimen was instituted:

At 8 a. m. the angles related to the gluteal or hamstring spasm were measured. Immediately thereafter the patients were given neostigmine methylsulfate. Atropine sulfate 1/100 to 1/200 grain (0.65 to 0.32 mg.) was administered hypodermically at the same time in an attempt to control parasympathetic reactions.

2. Watkins, A. L.; Brazier, M. A. B., and Schwab, R. S.: Concepts of Muscle Dysfunction in Poliomyelitis, Based on Electromyographic Studies, J. A. M. A. **123**: 188-192 (Sept. 25) 1943.
3. Moldaver, J.: Physiopathologic Aspect of the Disorders of Muscles in Infantile Paralysis: Preliminary Report, J. A. M. A. **123**: 74-77 (Sept. 11) 1943.

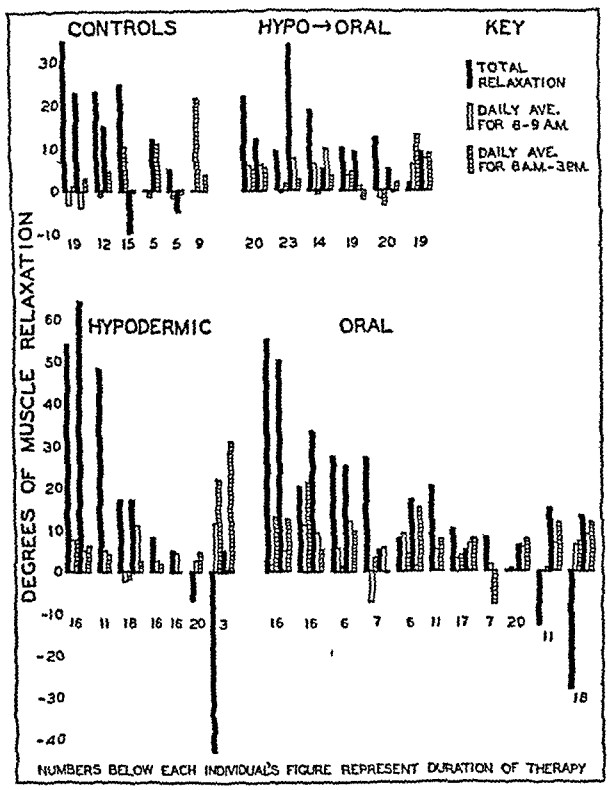
At 9 a. m. the angles were remeasured and the number of degrees of increase due to muscular relaxation were thus determined. Hot fomentations were then applied continuously to the involved muscles according to the Kenny technic until 3 p. m., when they were stopped and the angles again measured.

Two methods of administration of neostigmine were used in our study:

1. Thirteen of the patients received single daily subcutaneous injections of 1:2,000 neostigmine, the usual dose being 1.0 mg.

2. Six of these patients were changed to oral administration of the drug after four to thirteen days, and 11 additional patients received the oral neostigmine from the beginning of their therapy. The oral neostigmine was given twice daily, 30 mg. being given at 8 a. m., with 15 mg. at 6 p. m.

Six patients served as partial controls. Unfortunately some of these had received neostigmine for a portion of their therapeutic period. Three of these were treated with neostigmine for six, seven and eleven days respectively before it was discontinued and relaxation studied without its use. One patient was studied without neostigmine for the first nine days of hospitalization and was then treated with the drug for three days. A fifth patient recived 1.0 mg. of neostigmine on his second and third hospital days in an attempt to relieve bladder sphincter paresis. Only 1 patient received no neostigmine at all. The control patients received the continuous hot foments comparably to the other patients for six to seven hours each day, and the angles related to the muscles in spasm were measured at 8 a. m. and 3 p. m.



RESULTS

Within the first hour after neostigmine administration, several of the patients had drug reactions consisting of muscle spasm or twitching, abdominal sensory illusions, substernal pain, nausea, vertigo or emotional disturbances. These reactions, however, were not severe and the patients rarely complained unless questioned regarding the effects of the drug. In no case was it necessary to discontinue the neostigmine.

The details of the effects of the neostigmine therapy on the passive motion of spastic muscles are given in the accompanying table. Results are grouped according to the amount of neostigmine given and the method of its administration. Listed in the table are the average daily amounts of relaxation obtained at 9 a. m., one hour after the neostigmine administration and at 3 p. m., six hours later, after the continuous applications of the hot fomentations. These results are recorded separately for each muscle group measured, i. e. right or left hamstring or gluteal spasm, but each figure represents the average of several days of individual measurements. Also included in the table are the total changes in the degree of spasticity for each muscle group during the entire therapeutic period.

It is to be noted that there was not a constant relaxation of muscle spasm for any form of therapy or period of time. Some cases showed decided improvement, while other cases exhibited either slight or no improvement, and some even showed an increase in the amount of spasm. Often those who relaxed well during the day would have enough return of spasm at night so that the total change for the entire therapeutic period was less than might have been anticipated on the basis of one day's performance.

In view of this extreme variability, the use of averages is of questionable value; but we have presented this form of summary as a further aid for interpreting the results. The average relaxation of all patients one hour after giving the neostigmine was found to be 3.4 degrees, with a greatest relaxation for

Effect of neostigmine on muscle spasm: relaxation reported for right and left hamstrings or gluteal muscles for each patient.

any one muscle group for this hour of 39 degrees. The average relaxation for the day in the patients receiving neostigmine was 3.5 degrees, a figure which is comparable to the reduction of spasm which occurred during the first hour. One might conclude, therefore, that the neostigmine gave more relaxation than did the hot foments which were used later throughout the day or, on the other hand, that the effect of neostigmine was produced early rather than over a prolonged period of time. It must be remembered, however, that there is a natural impairment of mobility of joints following a night's sleep and that there would automatically be some improvement in passive motion during the 8 a. m. to 9 a. m. hour, regardless of whether or not any therapy had been given.

In the control series the average daily relaxation was 5.9 degrees, which is a better response than that for the neostigmine group. This must be interpreted as due to individual variability and an inadequate number of cases, since, if this relaxation had been due to hot fomentations alone, the results of the two series should have been comparable.

The average total amount of improvement in the patients receiving neostigmine from the beginning to the end of therapy was found to be 14.7 degrees. These overall results for neostigmine are somewhat higher than those of the control group, which had an average total increase of 10.3 degrees of relaxation. It must be pointed out, however, that the control patients were studied for a shorter period of time.

The variability of the effects of neostigmine is perhaps appreciated better from the graphic presentation of the data in the chart. The results have been plotted for the separate muscle groups, right and left, of each individual patient and show the total amount of relaxation in these muscles over the entire therapeutic period as well as the average changes for the first hour after administration of the neostigmine and for the whole day. It will be observed that the black columns for total relaxation vary considerably in height between individuals and have no relationship with the white or barred columns, which represent the average changes during the day.

Several factors must be considered in any attempt to explain the variability in our data. In addition to an inadequate number of cases and the resultant domination of individual differences, part of the apparent conflict in our data may have been due to the subjective element unavoidable with the angle measurements. In spite of our efforts to determine these angles accurately, the subjective element was important since the patients tended to show resistance to passive motion

Amount of Relaxation Produced in Spastic Muscles by Means of Neostigmine and Hot Fomentations

(Relaxation was determined daily by measuring the angle of passive motion obtainable with the spastic muscles)

* Measurements on these patients are for gluteal spasm. All other measurements are for hamstring spasm.
† These patients were studied both for control and for neostigmine periods.

by either voluntary or involuntary contraction of muscles during the examination, and the point at which passive motion would produce pain was not constant. Immediate repetition of the measurement occasionally gave an entirely different angle, which sometimes differed by as much as 100 per cent from the first measurement.

Another factor which may have influenced the results must also be considered. The duration of effect of neostigmine, as well as the difference in response due to mode of administration, need more careful study. Goodman and Gilman [4] state that hypodermic injections are believed to have an influence of at least six hours' duration, while oral neostigmine exerts its effect over a longer period.

The following case is presented briefly to show that there are inconsistent and irregular periods of relaxation of affected muscles in acute poliomyelitis which can appear at any time and disappear within a few hours. This further illustrates the fallacy of attempting to interpret accurately the relaxation of the spastic muscles.

L. A., a white youth aged 15 years, entered the hospital on Oct. 17, 1943, four days after the onset of the disease. His cerebrospinal fluid findings substantiated a diagnosis of acute anterior poliomyelitis. His initial muscle involvement was spasm of the neck extensors, sacrospinalis group and hamstrings, paralysis of the right quadriceps and left iliopsoas, and paresis of muscles for micturition. He received 1.0 mg. of neostigmine on October 17 and 1.0 mg. on the 18th. Representative angle readings for his left and right hamstrings were, on the 18th, 1 and 22 relaxation, respectively, for the day, on the 28th, 5 and 15 relaxation and on Jan. 30, 1944 1 and 0 relaxation.

The effects of neostigmine were studied on 4 cases of bulbar poliomyelitis also. All 4 of these cases were primarily bulbar in type, i. e. not of the ascending form but with the paralysis confined chiefly to the pharynx, larynx and palate, with loss of cough reflexes. Neostigmine injections of 1.0 to 1.5 mg. daily were given to these 4 patients. In addition, hot packs were applied to their necks, fluids were administered to combat dehydration, and scarlet fever convalescent serum and sulfonamides were used to combat pneumonitis. Beds were elevated at the foot to promote drainage of nasal and pharyngeal secretions. In spite of these therapeutic efforts, 3 of the 4 patients died, and no benefit whatever was noted from the neostigmine.

It will thus be seen that in our series of cases of acute poliomyelitis no pronounced or even consistent relaxation was produced by the neostigmine therapy. This was disappointing to us, since we felt that its use was based on sound pathophysiologic principles and also since Kabat and Knapp's work had been encouraging. It is probable that our results differed from those of Kabat and Knapp because all of our cases were acute in contrast to a predominance of chronic cases in their series. In spite of the discrepancies in our data, we wish to advance the following tentative conclusions, since we believe them to be justified on the basis of our observations:

1. Neostigmine produces a partial relaxation of the spastic muscles in a majority of cases of acute anterior poliomyelitis. The relaxation obtained with neostigmine is neither dramatic nor constant, is characterized by irregularity in response and is followed by a gradual return of spasm, which frequently reaches its initial level within twenty-four hours.

2. The combined use of neostigmine and hot foments in the treatment of acute anterior poliomyelitis results, in most cases, in a perceptible and persistent relaxation of spastic muscles, which is evident after several days of therapy and its further use is warranted.

3. Neostigmine appears to be of little value in bulbar poliomyelitis.

4. Goodman, L., and Gilman, A.: The Pharmacologic Basis of Therapeutics, New York, Macmillan Company, 1941, chapter 21, pp 378-388

SUMMARY

1. The effect of neostigmine on spastic muscles has been studied by the use of subcutaneous and oral doses of the drug in 24 patients with acute anterior poliomyelitis.

2. The degree of daily relaxation of the involved muscles produced by neostigmine was determined by measuring increases in passive motion one hour and seven hours after administration of the drug. Results for each patient were compared from day to day.

3. The total amount of relaxation obtained in the spastic muscles during the patient's entire therapeutic period was also determined and results were compared with a control group of 6 patients who did not receive the neostigmine. Both groups of patients had been given hot fomentation treatments according to the Kenny technic.

4. In these cases of acute poliomyelitis the neostigmine caused a partial relaxation of spastic muscles which was neither pronounced nor constant and which was characterized by irregularity. Nevertheless it was concluded that the combined use of neostigmine with hot fomentations resulted in a persistent and perceptible relaxation of spastic muscles in most of the cases of acute anterior poliomyelitis.

5. These observations are limited to the acute phase of poliomyelitis and not to the effect of neostigmine on the subacute or chronic phases of the disease.

ACUTE ANTERIOR POLIOMYELITIS

FINAL REPORT ON SEVENTY CASES TREATED IN 1943

MARY S. SHERMAN, M.D.

CHICAGO

In May of 1944 a preliminary report was made on the status of 70 patients six months after they had had acute anterior poliomyelitis during the Chicago epidemic of 1943.[1] These patients had had only general supportive therapy during the acute phase of the disease. The survey revealed that 10 per cent had enough residual weakness to require braces or future surgery, 72.8 per cent had no residual weakness or such slight weakness that it was barely detectable, and 8.6 per cent had functionally significant weakness which did not require further therapy and which did not constitute a handicap to a normal life. There were 8.6 per cent deaths.

The 64 survivors of this group have been followed carefully at short intervals, and it is now possible to present a report of their condition eighteen months after the acute disease.

No one of the 13 nonparalytic patients has developed any sign of weakness, spasm, stiffness or deformity. Seven patients who had had paresis but who had recovered completely at the end of six months have remained normal. Since then 19 other patients have recovered sufficiently so that no weakness is now demonstrable. Of this total of 26, 20 had originally moderate weakness and 6 (all of whom had severe bulbar involvement) had profound paresis. There are 12 others who have improved decidedly but who have remaining detectable though functionally insignificant

From the Department of Surgery, Division of Orthopedic Surgery, University of Chicago

1. Sherman, Mary S.: The Natural Course of Poliomyelitis. A Report of 70 Cases, J. A. M. A. 125:99-102 (May 13) 1944.

weaknesses. Two of these patients have very mild, well compensated and nonprogressive scoliosis which does not require treatment. All 6 patients who were listed as having functionally significant weakness which did not require further treatment have made sufficient recovery to be classed at present with those whose weaknesses are insignificant even though 2 of them limp slightly.

The 7 patients who after six months were considered to be candidates for braces or surgery are essentially unchanged and are still in the same group. Two are wearing long leg braces and 2 have flail arms which show no recovery, but only 1 is extensively handicapped. One arm will be restored to good function by a shoulder arthrodesis and 1 patient with a weak foot will be returned almost to normal by a foot stabilizing operation.

The accompanying table shows the comparison of results at six months and at eighteen months. It will be seen that at eighteen months 81.4 per cent of the total initial group or 89.1 per cent of the survivors have either no residual or slight weakness, and 10.9 per cent of the survivors have a handicap which will require braces or surgery.

Status of Patients Six Months and Eighteen Months After Illness

	Total Group		Survivors Only	
	6 Mos.	18 Mos.	6 Mos.	18 Mos.
1 No detectable weakness at any time	13 (18.5%)	13 (18.5%)	13 (20.3%)	13 (20.3%)
2 Those who had paresis but are not now handicapped	38 (54.3%)	44 (62.9%)	38 (59.4%)	44 (68.8%)
a. No detectable weakness now....	7	26	7	26
b Functionally insignificant weakness	31	18	31	18
3 Functionally significant weakness which requires no further therapy	6 (8.6%)	0	6 (9.4%)	0
4 Severe weakness requiring braces or surgery	7 (10%)	7 (10%)	7 (10.9%)	7 (10.9%)
5 Deaths (4 bulbars, 2 spinal).....	6 (8.6%)	6 (8.6%)		

COMMENT

No patient has regressed. This is probably attributable not so much to the degree of recovery as to the detailed early evaluation of the patient's muscular state.

Major improvements, as was expected, have occurred, without exception, in those patients who had not been completely paralyzed. In all patients but 1 the subsequent course has agreed with the prognosis made when the acute phase had subsided. This 1 patient was expected to be grossly handicapped but has made a spectacular recovery.

The later course of these patients supports further the recently ignored fact that the amount of ultimate recovery depends primarily on the extent of initial involvement of the central nervous system and not on the type of treatment.

950 East Fifty-Ninth Street, Chicago 37.

Medical Institutions in Japan.—In 1937 there were nineteen government controlled medical schools and nine private medical schools. In the same year there were eight dental colleges. Diagnostic, research and biologic laboratories are almost exclusively government controlled or operated. There are several charitable organizations in Japan that are interested in public health, most notable of which is the Red Cross.—Simmons, James S., and others: Global Epidemiology, Philadelphia, J. P. Lippincott Company, 1944.

OSTEITIS CONDENSANS ILII

HUGH F. HARE, M.D.
AND
G. EDMUND HAGGART, M.D.
BOSTON

Osteitis condensans ilii is a term applied to the alteration of the bony architecture of the iliac bone adjacent to the sacroiliac joint. The condition is characterized by condensation of the involved bone without involvement of the joint space or adjacent sacrum. During the year 1943, 23 patients presenting these changes were seen in the clinic. Since the condition has been described infrequently, a study of the clinical manifestations was undertaken to determine whether a clinical syndrome accompanied or produced this roentgenographic change.

A review of the literature relative to osteitis condensans ilii revealed that the first article appeared in 1926, at which time Sicard, Gally and Haguenau [1] reported 5 cases, describing accurately the roentgenograms. They stated that they did not know the etiology. In 1928 Bársony and Polgár [2] in an article on the condition were not sure that it was a clinical syndrome but described the changes in the iliac bone quite satisfactorily as a sclerosing type of bone lesion. In 1932 Berent [3] in a report stated that it was his belief that the disease was the result of pregnancy and that he had seen it only in women following childbirth. He presented 3 cases, all with some injury prior to or during delivery as a result of (1) premature rupture, (2) the use of high forceps and (3) acute pain during delivery. This hypothesis has been partially disproved, as the condition has occasionally been diagnosed in the male patient.[4] Berent's experience has been similar to ours in that all patients have been women, but not all gave a history of pregnancy.

In 1936 Rendich and Shapiro [4] carefully reviewed the literature and reported their cases. In 1 case fusion of the sacroiliac joint was carried out, at which time a biopsy of the involved bone was taken and the report of Dr. William Hala [4] was as follows: "There is marked condensation of the osseous tissue with obliteration of the evident former lacunae. There appear to be no osteolytic or osteoclastic changes in the bone and neither is there any evidence of overactivity of the osteoclasts or osteoblasts. In fact, these cells are more or less conspicuous by their absence. The marrow spaces contain an unusual number of myocytic and plasma types of cells. The significance of the plasma cells is undetermined. In general, the lesion appears to be of an osteitis condensans type. It is apparently independent of any inflammatory or other etiology so far as can be ascertained from the histology of the specimen. Occasionally, in the condensed bone there appear to be depositions of lime salts which occur more or less in irregular linear areas, but more or less parallel to the lamellae of the bone." Rendich and Shapiro did not attempt to describe the condition as a clinical entity but simply stated that the symptoms were vague and the physical findings scant and not informative.

From the Department of Radiology (Dr. Hare) and the Department of Bone and Joint Surgery (Dr. Haggart), the Lahey Clinic.

SYMPTOMATOLOGY AND PHYSICAL FINDINGS

Recurrent attacks of chronic low back and pelvic pain were the most common complaints. In most instances the pain was more severe in one sacroiliac than in the other. In 10 cases pain remained localized, whereas in 13 cases it extended down one thigh. Attacks of pain in most instances were brought on by bending forward or by lifting. These attacks lasted from two weeks to several months, during which time the patient was incapacitated, and with each subsequent attack the pain became more severe.

In 8 of the 23 cases, and probably in more although the history does not record it, the onset of symptoms was noted just prior to or following delivery. In no instance was there a history of severe trauma. The history of onset in the other cases was vague. In 2 cases the onset followed minor falls. Two other patients noted their first pain at the onset of the menstrual period. All patients were women within the child-bearing age, the average age being 30 years. The oldest patient was 38, the youngest 23 years of age.

In our group the duration of symptoms before diagnosis varied from seven months to fifteen years; the average was three years. Obesity was not a factor. The weight varied from 104 to 211 pounds (47 to 96 Kg.); the average weight was 146 pounds (66 Kg.).

The physical findings have not been significant with the exception that all patients presented constitutionally inadequate musculature and in only 4 cases was a positive straight leg test elicited. In these 4 cases a diagnosis of herniated disk was considered, and 1 patient was operated on for herniated disk without relief of symptoms. Since operation the symptoms have become progressively worse over a period of two years.

The sacroiliac test was positive in all cases, but, since the value of this test is questionable, no conclusion may be drawn from it at present.

LABORATORY DATA

In 2 instances the blood sedimentation rate was increased above normal. In 1 case only a transitory rise was noted, with subsequent return to normal. All other laboratory tests gave consistently negative results.

DIFFERENTIAL DIAGNOSIS

The most important single differential diagnosis to be made is to distinguish osteitis condensans ilii from arthritides, especially the Marie Strümpell type, which is similar in appearance roentgenographically and represents the category in which these patients have in the past been placed. In both diseases the pain may grow progressively worse, but in osteitis condensans ilii the disease, as far as we have observed it, has remained localized to the affected ilium, while in nearly all cases of arthritis the disease has slowly progressed to involve the entire spine. Rheumatoid arthritis of the Marie-Strümpell type occurs predominantly in the male, while osteitis condensans ilii has in our experience been present only in the female. In rheumatoid arthritis the sedimentation rate is consistently and persistently elevated, which has not been true in our present series of cases of osteitis condensans ilii.

Summary of Twenty-Three Cases

Case No.	Age, Years	Onset	Radiation	Straight Leg Test	Duration, Years	Sedimentation Rate	Weight, Pounds	Comment

Pain in low back and pelvis..... 23 cases
Radicular pain..... 13 cases

ETIOLOGY

The cause of this disease is unknown. One theory presented previously is that following trauma, usually of childbirth, there is interference of blood supply to the inferior margin of the ilium adjacent to the inferior margin of the sacroiliac. The blood supply to this particular portion of the ilium is not well described, but in the roentgenogram the nutrient arteries are seen to lie lateral to the bone usually involved.

TREATMENT

Conservative treatment consisting of rest, baking and massage and a supportive belt is usually successful in relieving the periodic attacks of pain. In some instances, however, the disease is incapacitating. Bending will bring on an attack which will require days to weeks of bed rest and care to alleviate. In these instances and in those cases in which relief is not obtained by conservative measures, operative fusion of the sacroiliac joint should be considered.

THE ROENTGENOGRAM

Routine roentgenograms of the lumbosacral spine do not show the sacroiliac articulations in their entirety, and because this condition appears most frequently in the female in whom the sacrum tends to be of the

horizontal type, special views of the sacroiliac articulations are essential before correct interpretation can be made. We routinely take a 45 degree angle view of the sacroiliac joint in all cases in which the symptoms are referable to the lumbar spine in order that we may see the sacroiliac articulations and the sacral foramens in their entirety. The 45 degree angle view has been well described on numerous occasions and need not be described further except to say that it is an essential exposure in order to make a correct diagnosis of disease of the sacroiliac articulations.

In a study of the sacroiliac articulations in cases of osteitis condensans ilii it is well to remember that the auricular portion of the ilium extends behind the anterior edge of the sacroiliac joint, so that the portion of the ilium which lies behind the sacrum may give the appearance of disease of the sacrum and even of the joint. As the name implies, osteitis condensans ilii is characterized by dense sclerotic bone with obliteration of the trabeculae of the auricular portion of the ilium and the portion of the ilium adjacent to the sacroiliac articulation. The line between normal and abnormal bone is distinct. The abnormal bone is similar to that seen with Garré's sclerosing osteitis and appears on the roentgenogram as if this portion of bone were underexposed. The disease in all of our cases was symmetrical, although in some of the cases previously reported it was limited to one ilium and there are reported cases of the disease in the low lumbar vertebrae, in the os calcis and in the femurs. Perhaps the disease seen in other bones may have been the result of a mono-osteitic type of Paget's disease or of embolic manifestations.

The important finding on the roentgenogram, then, consists of dense bone involving the auricular portion of the ilium and the portion of the ilium adjacent to the sacroiliac articulation. The degree of involvement may vary in individual cases, but in all cases the articulation remains intact and the sacrum is not involved, as shown in the accompanying table.

REPORT OF CASES

CASE 1.—A woman aged 38 entered the clinic on April 23, 1943 complaining of pain in the lower part of the back and in the left thigh of twelve years' duration. About twelve years before entry she fell backward, stretching her left leg. This was followed immediately by pain in the left thigh. The pain disappeared but soon episodes of pain in the low back began, with extension down the left thigh and up between the shoulder blades, accompanied by pain extending down to the left foot posteriorly, not aggravated on coughing or sneezing. The pain was severe at night, and sleeping on a hard bed gave no relief. Two years before she entered the clinic the coccyx had been removed because of pain. The pain had persisted following operation and had been severe enough to keep the patient from working. She stated that if she bent over to pick up something the leg became so sore that she was unable to walk for a few days She had had one child prior to the onset of pain.

Physical examination revealed that the patient was obese and of chunky build. The back motions were free of pain. The straight leg raising test gave negative results bilaterally. The ankle and knee jerks were sluggish Over all of the back and especially over the iliac crest there was tenderness superficially, worse on pinching a mass of subcutaneous fat. The tenderness was present also on the lateral side of the left thigh. On direct pressure over the left sciatic notch there was tenderness, but this was present also on pinching the fat mass and did not occur on pressure farther down the course of the sciatic nerve. There was subcutaneous tenderness over the back up to the shoulders. The patient had gained 30 pounds (13.6 Kg.) in fourteen months.

Laboratory examination revealed hemoglobin 101 per cent, red blood cell count 4,820,000, white blood cell count 7,700, differential count normal. The Hinton test gave negative results. The sedimentation rate was 18 mm. per hour.

A diagnosis was made of lumbosacral arthritis and sclerosing osteitis of the ilia, and the patient was advised regarding weight reduction, physical therapy and muscle training.

Roentgenograms taken of the lumbosacral spine showed asymmetrical facets of the lumbosacral region, with some narrowing of the intervertebral space of the lumbosacral junction with reaction on the right (fig. 1). There was increased density around both sacroiliac joints on the iliac side, more pronounced on the right, as a result of sclerosing osteitis. The coccyx had been removed. The roentgenologist's interpretation was lumbosacral arthritis with sclerosing osteitis of the ilia.

FIG. 1.—Osteitis of lower third of the ilium adjacent to the sacroiliac joint, with slight involvement of the auricular portion. The sacroiliac joint appears normal. The lesion is symmetrical.

CASE 2.—A woman aged 31 entered the clinic on Nov. 8, 1943 complaining of backache of seven years' duration and vaginal discharge of two years' duration. About six months following the birth of her first child, seven and a half years before, she first noticed back pain. The difficulty was not associated with lifting or moving. The pain was relieved by wearing a girdle throughout the day. She had a feeling as though her "insides were going to fall out," a sensation that "something would come out of her vagina during evacuation." Frequency and urgency of urination were present. Two and a half years before coming to the clinic, and about six months following the birth of the second child, she noted a vaginal discharge.

Laboratory examination revealed hemoglobin 104 per cent, red blood cell count 5,000,000, white blood cell count 10,000, differential count normal. The Hinton test gave negative results. The sedimentation was 8 mm. She weighed 107 pounds (48.5 Kg.).

The patient was seen by members of the Department of Bone and Joint Surgery, who made the following note: The

patient described a low grade backache localized to the left sacroiliac area with occasional reference to the left gluteal area and left sciatic notch. Pain was present much of the time. There was no sciatic pain. The spine motions were normal. There was tenderness over the left sacroiliac region, the left gluteal region and at the left iliolumbar ligament. The sacroiliac test gave negative results. Reflexes were normal. There were no sensory changes.

Roentgenographic examination was made (fig. 2) and the roentgenologist's report was as follows: "Anteroposterior and lateral views of the lumbosacral spine show condensing osteitis of both iliac bones. The process is symmetrical. The sacrum appears to be normal. The joint spaces are normal. Interpretation: Condensing osteitis of the ilia."

The patient was advised to continue the use of the back brace and to have physical therapy.

CASE 3.—A woman aged 28, mother of 1 child, first came to the clinic on Sept. 8, 1939 complaining of backache of eight years' duration and a tired feeling in the lumbar spine. The pain extended to the umbilicus and sometimes up between the shoulders and was worse with menstrual periods. It was present in the morning before arising but was relieved somewhat after she was up and had put on a girdle. It recurred in the afternoon. Weather did not affect the pain. At the age of 16 years she was first seen by an orthopedic consultant, who said that her pelvis was not properly alined. She stated that she may have had poliomyelitis at the age of 9 years.

The patient was examined by members of the Department of Bone and Joint Surgery. The spine was flexible. The pelvis was tilted down to the left. The left shoulder was slightly lower than the right. Lumbar lordosis was exaggerated. There was no gross paralysis in the extremities. A ¾ inch lift under the heel was advised and roentgenograms of the lumbosacral spine were ordered (fig. 3).

Fig. 2.—Osteitis condensans ilii showing involvement of the middle two thirds of the ilium adjacent to the sacroiliac articulation. This shows sharp demarcation between normal and abnormal bone and normal joint space.

The roentgenologist's report was as follows: "The anteroposterior and lateral views of the dorsal and lumbar spine show a scoliosis convex to the left in the lumbar region, with rotation of the body to the side of the curve. The bones of the lumbar spine otherwise appear normal. There is moderate reaction around both sacroiliac joints, more marked on the right. Interpretation: Scoliosis of the lumbar spine and bilateral sacroiliac arthritis."

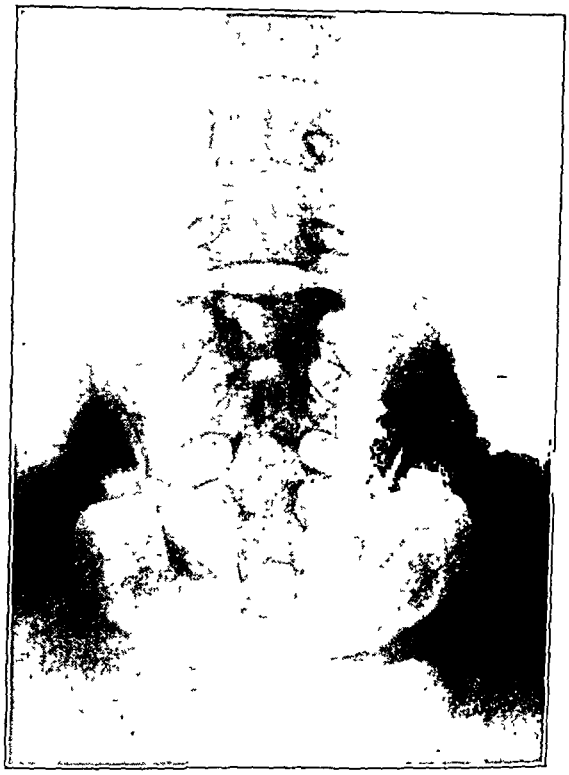

Fig. 3.—Osteitis condensans ilii with involvement of the entire ilium adjacent to the sacroiliac joint.

The hemoglobin was 80 per cent and the red blood cells numbered 3,900,000. The Hinton test gave negative results. In addition to the lift to the heel, infra-red treatment was given.

The patient was not seen again until Dec. 8, 1943, at which time she complained of pain in both hips and in the lower part of the back. She stated that she had never had an acute attack of pain; it had been referred down the posterior aspect of the legs to the foot but never to the toes. Coughing and sneezing had no effect. Standing or riding horseback produced a tired feeling with achy pain. The backache increased just before and during the menstrual period. About one year before her second visit she began having pain in both hips, more noticeable on assuming the erect position after sitting for a while. After she moved about the pain was relieved, but the attacks had become progressively worse.

On examination the patient appeared to be well nourished and intelligent. She weighed 123 pounds (56 Kg.) and was 5 feet 4 inches (163 cm.) tall. At this time there was slight lumbar scoliosis.

Blood examination revealed hemoglobin 98 per cent, red blood cell count 4,260,000 and white blood cell count 7,800. The differential count was normal. The sedimentation rate was 15 mm. per hour.

The spine was again studied. Anteroposterior and lateral views of the lumbosacral spine, pelvis and hips showed a bilateral condensing osteitis limited to the iliac bone. Otherwise the bones were normal, except for a rotary scoliosis of the lumbar spine to the left.

This patient, followed over a period of three years, has not obtained relief of pain, which has definitely increased during the last year.

CASE 4.—A woman aged 31 came to the clinic complaining of low back pain and sciatica of three years' duration. There was no history of injury. The onset was about three years previous to entry, at which time she stooped to pick up something and was then unable to straighten up. She was in bed for about one month following this attack. Since then she had had two or three attacks precipitated by lifting or stooping. The pain was in the low back and was dull and aching in character, with sharp pain running down the back of the right thigh, through the posterior portion of the calf and the ankle. It was relieved when she rested and was worse on coughing and sneezing during an acute attack. She also had pain in the upper portion of the spine, extending down the spine She had had four pregnancies

On physical examination the patient was 5 feet 4 inches (163 cm) tall and weighed 190 pounds (86 Kg). She was obese and had a waddling gait Physical examination was not significant other than for tenderness over the lumbosacral spine, inadequate musculature and increased lumbar lordosis.

The patient was advised to wear a low back support and was referred to the Department of Internal Medicine for a reduction regimen.

Laboratory examination revealed hemoglobin 98 per cent, red blood cell count 4,890,000, white blood cell count 7,150 and a normal differential count. The Hinton test gave negative results The sedimentation rate was 1 mm. in one hour. Roentgenographic examinations of the lumbar spine, anteroposterior and lateral views, showed a moderate osteitis of both sacroiliac joints without narrowing of the joint space (fig. 4). The bones otherwise appeared normal

Fig. 4.—Osteitis condensans ilii showing involvement of the lower two thirds of the ilium.

The patient was seen again eleven months later She had lost 23 pounds (10 Kg.) but the backache and sciatica had continued

CASE 5.—A single woman, aged 26, first came to the clinic on Jan 15, 1943 complaining of pain in the left buttock of three years' duration. The pain extended halfway down the thigh There was low backache, which was worse on coughing. Three weeks before entry she had had the most severe attack of pain; it had disturbed her sleep and had been present on arising in the morning.

Physical examination revealed that the patient appeared to be healthy and was not in obvious distress. She weighed 118 pounds (53.5 Kg.). Examination gave negative results except for slight pain on the left on attempting the leg raising test.

Fig. 5.—More advanced stage of disease, with involvement of the auricular portion of the ilia.

Laboratory examination revealed hemoglobin 96 per cent, red blood cell count 4,730,000 and white blood cell count 8,700. The differential count was normal. The Hinton test gave negative results. The sedimentation rate was 63 mm. per hour.

The roentgenologist's report was as follows: Anteroposterior and lateral views of the lumbosacral spine, pelvis and hip showed a low grade dense osteitis of both sacroiliacs, the process being symmetrical. There was slight narrowing of the joint spaces (*fig. 5*). The bones otherwise were normal.

COMMENT

This series of 23 cases in which the chief complaint was recurrent attacks of chronic low back pain represents a group in which in the past the diagnosis has been arthritis. In 8 of the 23 cases the pain occurred following or during pregnancy and in 8 cases there was radicular pain. The roentgenographic changes noted were common to all 23 patients, namely a condensation of bone of the inferior medial margins adjacent to the sacroiliac articulation, with the joint space and sacrum remaining normal.

The etiology of osteitis condensans ilii is unknown and any attempt to explain the cause of the pain resulting from these changes has been unsatisfactory. These cases must not be placed in the category of chronic arthritis.

Conservative treatment, namely heat and massage, has in most instances relieved the periodic attacks of pain, but for those patients who have long periods of incapacitation, operative fusion of the sacroiliac articulation on the painful side might justifiably be considered.

THE AMERICAN RED CROSS

ANNOUNCEMENT OF NEW POLICY GOVERNING THE PARTICIPATION OF RED CROSS CHAPTERS AND CIVILIAN BLOOD DONOR SERVICES

DEVELOPMENT OF THE POLICY

As early as 1937 the American Red Cross authorized a few selected chapters to carry on an experiment in the enrolment of volunteer blood donors to be available on call from hospitals and physicians for blood donations free of charge to those not able to pay for them. Under the stimulus of the war, the blood plasma program of the Office of Civilian Defense and the Red Cross blood donor service for the armed forces, a demand arose from many communities for local blood or plasma banks for civilians. The national organization responded in March 1942 by providing that, on approval by the national medical director, chapters might participate in such undertakings on certain specified conditions. Chief among these were the requirements that the project must be sponsored and operated by the local medical society, the city or state health department or a specially qualified hospital laboratory and that the chapter's participation must be limited to the procurement of volunteer blood donors and the services of its volunteer workers.

By 1943 state departments of health had become interested in the establishment of statewide blood donor services. In Michigan Red Cross chapters were authorized to cooperate with the state department of health under the conditions prescribed for local blood and plasma banks.

By 1944 the successful use of plasma and other blood derivatives for the armed forces and the association of the American Red Cross with the procurement of blood for this purpose had resulted in a widespread demand that the Red Cross, out of the abundance of its experience, render a similar service to the civilian population. The Medical and Health Advisory Committee of the American National Red Cross recommended that a study be made as to the need for continued Red Cross activity in civilian blood donor services. Accordingly, the study was undertaken and consultation held with the United States Public Health Service, the Board of Trustees of the American Medical Association, the Conference of State Medical Society Secretaries and editors of state medical journals, the Association of State and Territorial Health Officers, the American Hospital Association and others. There was general agreement that the Red Cross should authorize its chapters to cooperate with state and local health departments and other reliable medical and health agencies in the procurement of blood for civilian use.

By 1945 several states, cities and counties were engaged in or planning programs to supply blood and blood derivatives for civilian use, and chapter participation in a dozen or more of these programs had already started or was under discussion. The special Medical and Health Survey Committee of the American National Red Cross reviewed the whole matter and made detailed recommendations to the chairman concerning a sound basis for Red Cross participation in civilian blood donor services. The question was carefully considered also by the administrative and technical staffs of the American National Red Cross, with the result that previous instructions governing the participation of chapters in local blood or plasma banks have been superseded by the following policies, principles and procedures.

THE POLICY

Chapters of the American Red Cross desiring to do so may participate in civilian blood donor services only on the receipt of authorization from the area manager. Such authorization may be granted only when the following conditions are met:

(*a*) That the responsibility for technical operations, staff and equipment rests with a reliable medical or health agency.

(*b*) That participation of the chapter is limited to the recruitment or enrolment or both of volunteer donors and the provision of nontechnical staff and equipment.

(*c*) That the community is not serving as a source of blood for the Army and the Navy or, if it is, that the amount of blood required for civilian needs is obtainable over and above the needs of the armed forces.

(*d*) That participation of the chapter is limited to one program of volunteer blood donor service for civilians in any one community. If two or more medical or health agencies wish to sponsor programs in the same locality with Red Cross participation, a joint arrangement shall be developed.

(*e*) That the sponsoring medical or health agency meets the minimum technical standards specified by the American National Red Cross. These will be prescribed, in conformity with all applicable government requirements, by a national advisory committee of specialists in the field of blood transfusion and blood substitutes to be appointed by the chairman of the American National Red Cross.

(*f*) That the service as set up in each individual case is officially approved by the health department having jurisdiction, the appropriate medical society and the hospital agency.

(*g*) That the service is designed to serve all acceptable hospitals and clinics and all physicians licensed to practice medicine and surgery in the communities where the service is conducted.

(*h*) That no charge is to be made physicians, hospitals, clinics or patients for the blood or blood derivatives produced under the program. In other words, the costs of donor recruitment, donor center operation, the collection and transportation of blood, the processing of plasma and other by-products, and the distribution of whole blood and its derivatives must be met by other means than a charge to physicians, hospitals, clinics or patients for any of the products furnished for use.

(*i*) That the care and protection of donors is to be wholly the responsibility of the sponsoring medical or health agency.

(*j*) That the sponsoring medical or health agency agrees that the cooperating chapter or chapters will be the sole donor recruitment and enrolment agency for the program. This will avoid the confusion of the public and the consequent loss of effectiveness of appeal that would ensue if responsibility should be shared with other agencies in the community. However, it should be understood that cooperative relationships may be established with local agencies which are interested in assisting the chapter by recruiting donors from their personnel or their constituencies.

(*k*) That blood donors are to be recruited on a voluntary basis and blood is not to be accepted from any person paid to donate.

(*l*) That the Red Cross is to be responsible for seeing that there is adequate publicity for donor recruitment, to acquaint the public with the purposes for which its blood is to be used.

(*m*) That the chapter is in a position to finance its part of the project without financial assistance from the national organization.

(*n*) That the American National Red Cross is permitted to draw on reserves of blood or blood derivatives as occasion may require for use in disasters or other emergencies.

ADMINISTRATION OF THE PROGRAM

1. *In Chapters.*—An application for authorization to participate in a civilian blood donor service must be submitted by the chapter chairman to the area manager for approval before the chapter may take part in such a project. When authorization from the area manager has been received, the chapter will appoint a Civilian Blood Donor Service Committee to conduct and supervise the chapter program. This committee should include representatives from appropriate chapter services, the medical society, the health department and the hospitals. The chapter committee on Civilian Blood Donor Service will look to the area medical director for advice and guidance in the conduct of the program.

2. *In the Area Offices.*—The conduct of the program in the areas is a function of the area medical director. He will maintain liaison with public and private medical and health agencies operating programs to supply blood and blood derivatives and will supervise the civilian blood donor service operations conducted by the chapters.

3. *At National Headquarters.*—Under the general supervision of the national medical director, the director of Civilian Blood Donor Services will maintain liaison with the national advisory committee of specialists in the field of blood transfusion and blood substitutes. He will prepare the technical standards for the guidance of the sponsoring medical and health agencies in the procurement and processing of human blood, and the necessary basic instructions covering the policies and procedures for the guidance of chapters in the procurement and enrolment of donors. He will give general supervision to the operation of the program and will be available as a technical consultant through the area offices.

CHAPTER PARTICIPATION

Authorization will be granted to Red Cross chapters to participate in civilian blood donor services only in case the chapter and the sponsoring agency meet the terms and conditions stipulated by the American National Red Cross. This requirement is in the interest of giving to the civilian population the benefit of the intensive experience gained by the American National Red Cross and the agencies associated with it in the operation of its blood donor service for the armed forces. It will also encourage the establishment, on a nationwide basis, of proper standards of donor procurement and enrolment and of blood procurement and processing. The continuance of the American Red Cross in the field of blood donor service, for which its name and emblem have virtually become the symbol during the war, should inspire public confidence and stimulate a more ready response on the part of volunteer blood donors. This should facilitate the widest possible distribution of the products of blood donor services to those who need them.

Medical and health agencies which now have or are planning a program to furnish blood and blood derivatives for civilian use and are interested in obtaining the assistance of Red Cross chapters should contact their chapter if the territory the program is to serve is within an individual chapter's jurisdiction, or the appropriate area office of the American National Red Cross if the program is to serve a territory involving the jurisdiction of more than one chapter.

Clinical Notes, Suggestions and New Instruments

EOSINOPHILIC GRANULOMA OF BONE

HARRY A. SOLOMON, M.D., AND SHELDON SCHWARTZ, M.D.
NEW YORK

Eosinophilic granuloma of bone was reported simultaneously in 1940 by Otani and Ehrlich [1] and by Lichtenstein and Jaffe.[2] Since then about 30 cases of this condition have been described.

Eosinophilic granuloma is a destructive bone lesion, which may be either single or multiple. It is characterized histologically by the presence of large mononuclear cell histiocytes and collections of eosinophils. The prognosis of the lesion is excellent.

ETIOLOGY

The cause of the condition is unknown. Trauma has been felt to be responsible by some; others have postulated a virus infection. The lesion is generally considered to be of an inflammatory nature, although all attempts to isolate an organism from the lesion have been unsuccessful.[3]

Eosinophilic granuloma is seen most commonly in children and in young adults. Males are more frequently affected.

CLINICAL FEATURES

The symptomatology is referable primarily to the skeleton.[4] The lesions are often solitary, involving the bones of the skull or pelvis and the vertebrae, ribs or long bones. Flat bones are more often involved. Cases with multiple lesions have been reported, as many as twenty-five in 1 case.[4] Patients complain of pain, swelling and tenderness in the region of the bony destruction for several days to months before the condition is discovered. Other symptoms that may be encountered are muscle spasm and muscular atrophy. Lesions may be asymptomatic and picked up only by x-ray examination. When multiple lesions are present, only few of them may cause discomfort. There may be slight fever, some elevation of the leukocyte count, anorexia and weight loss. Eosinophilia of 4 to 11 per cent has been observed in some cases. All of the blood chemical findings are characteristically normal.

X-ray examination reveals a destructive, well localized lesion.[5] In Farber's [4] series the lesion did not expand the cortex but some eroded it. The lesions developed rapidly and showed little periosteal reaction. Jaffe,[3] however, reports that in areas of cortical perforation periosteal bone formation is noted. He also observed expansion of the cortex. The bone destruction may result in spntaneous fracture.

PATHOLOGY

Characteristically, in the early stage, when the patient first has complaints, the lesion appears cystic and hemorrhagic and contains a soft yellowish brown material. Microscopically the lesion is granulomatous. Sheets of large, pale mononuclear

5. Hatcher, H.: Eosinophilic Granuloma of Bone, Arch. Path. **30**: 828 (Sept.) 1940.

cells with granular cytoplasm are seen, which may have finely vacuolated cytoplasm or appear "foamy." Eosinophils are also seen scattered throughout, either singly or in clumps. These may be seen in the early stages and be absent in the healing stage. Phagocytic giant cells may be observed near the necrotic material. A sprinkling of lymphocytes, plasma cells and polymorphonuclear leukocytes may be seen, but there is no abscess formation. The characteristic cell is not the eosinophil but the large mononuclear cell.

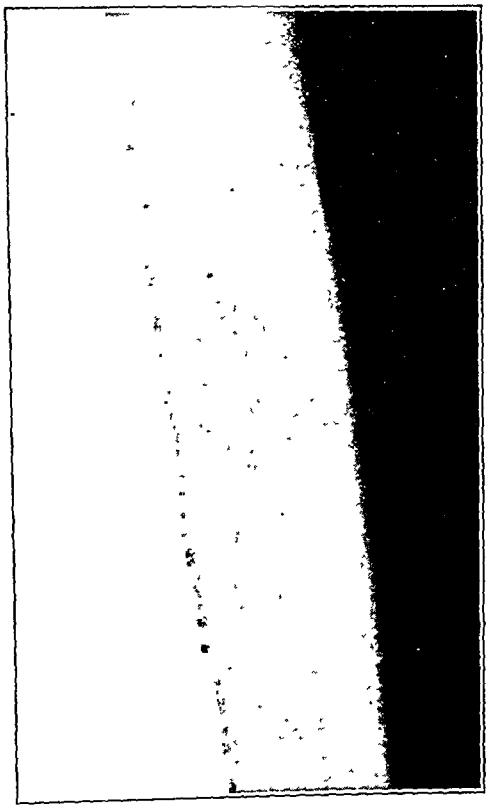

Fig. 1.—Lesion of eosinophilic granuloma in the shaft of the femur. The lesion is circumscribed and shows destruction of the cortex. The periosteal reaction is not readily seen in this view.

According to Farber the variation in the histologic picture represents stages in the evolution of the lesion. In the early destructive stage mononuclear cells, eosinophilic leukocytes and myelocytes, lymphocytes, plasma cells and neutrophils are seen. In the intermediary stage the eosinophils have disappeared and "foam" cells are noted. In the late stage there is replacement by connective tissue and eventually bone formation. Healing may also occur simply by resolution.[3]

TREATMENT AND PROGNOSIS

Eosinophilic granuloma runs a benign course, with recovery in all reported cases. However, if multiple lesions are present the prognosis must be guarded because visceral lesions may also be present and the patient have Hand-Schüller-Christian's disease.[4]

The treatment is entirely empirical. Good results have been obtained after curettage or after small doses of radiation. It has been shown that some cases with multiple lesions will heal spontaneously if left alone. Biopsies from solitary lesions are often made to prove the diagnosis. This procedure is equivalent to curettage. Often this procedure results in prompt relief of the pain. It is advisable to remove all recognizable pathologic tissue while doing the biopsy, unless it involves great technical difficulties or if the lesion is too extensive. Both treated and untreated lesions resolve in several months to a year.

REPORT OF CASE

Clinical History.—R. P., a white youth aged 17 years, was admitted to Bellevue Hospital complaining of pain in the left knee and anterior portion of the left thigh for two months. Six months before admission he contracted gonorrhea, which was successfully treated with sulfonamides. He was asymptomatic until two months before admission. Since the onset of his present illness he was treated at the outpatient department of another hospital as having gonorrheal arthritis. He had lost 18 pounds (8 Kg.) in the past two months and felt weak and tired. At the time of admission he was unable to bear weight on his left foot.

The systemic review was negative. The past history, other than that mentioned, was not pertinent. The family history was noncontributory.

Physical Examination.—The patient was fairly well nourished. He was in obvious distress, complaining bitterly of pain in the left knee and anterior portion of the left thigh. The knee was not swollen or reddened. There was only slight pain on movement and no reduction in the range of motion. The left thigh was not red or swollen. However, palpation revealed an area of extreme tenderness over the bone at the junction of the middle and upper thirds. No mass could be felt on admission, but a definite mass could be felt in this location after two weeks of hospitalization. The remainder of the physical examination detected nothing unusual. There was no urethral discharge, and prostatic massage yielded no fluid.

Laboratory Examination.—The temperature on admission was 99.4 F. and remained about 100. The leukocyte count was 12,400, with 62 per cent polymorphonuclear leukocytes, 34 per cent lymphocytes and 4 per cent monocytes. The red blood cell count and hemoglobin were normal. The blood calcium, phosphorus, acid and alkaline phosphatase and cholesterol were normal.

X-ray examination of the left thigh revealed a single, well circumscribed, intramedullary destructive process involving the left femur at the junction of the middle and upper thirds, with osteoperiosteal proliferation. X-ray examination of the left knee and hip as well as the remainder of the skeleton gave normal results.

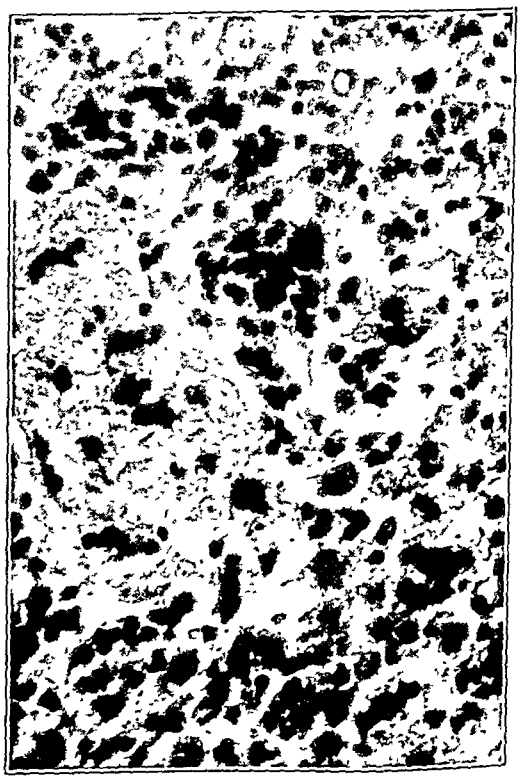

Fig. 2.—Section of tissue curetted from the lesion of the femur seen in figure 1. Large mononuclear cells with pale staining nuclei are seen throughout. The clumps of dark cells represent eosinophils.

Course.—In view of a solitary destructive bone lesion in a young adult, the diagnoses of Ewing's tumor or eosinophilic

granuloma were postulated. Those favoring the diagnosis of Ewing's tumor felt that large doses of radiation were indicated as soon as possible, because of the almost uniform fatality of the tumor. Biopsy was thought to be contraindicated because of the possibility of spreading the tumor. Those favoring the diagnosis of eosinophilic granuloma felt that a biopsy was justifiable before instituting radical therapy. It was decided to do a biopsy. Up until this time the patient required constant sedation because of the pain in the left leg. An incision was made in the anterior portion of the left thigh and a large portion of the bony lesion and underlying marrow were removed. The marrow was yellowish brown and appeared necrotic. The wound healed promptly and the postoperative course was uneventful. Almost immediately following biopsy the patient's pain entirely disappeared; his appetite increased and he started to gain weight. His temperature fell to normal and remained there. His leukocyte count also returned to normal. Repeated differential examinations of the blood failed to reveal any eosinophils. X-ray examination of the lesion one month after biopsy showed considerable reduction in the size of the lesion. The patient was able to walk without pain at this time.

Pathology.—The pathologic report was eosinophilic granuloma of bone. The histologic sections revealed granulation tissue composed principally of large mononuclear cells with granular, faintly staining cytoplasm and oval or reniform nuclei. There was extensive necrosis of portions of the tissue. Scattered throughout the granulation tissue were many eosinophils and a moderate number of plasma cells, lymphocytes and polymorphonuclear leukocytes. Periosteal bone formation was rather conspicuous.

COMMENT

The importance of eosinophilic granuloma is in its differential diagnosis. Because of the x-ray appearance it may be indistinguishable from a neoplastic or other inflammatory lesion. Lesions have been found in all bones except those of the hands and feet. In the case of a solitary lesion in a long bone the site of the lesion is of importance in the diagnosis. If the lesion is in the epiphysis, giant cell tumor should be excluded; this usually occurs in an older age group. Lesions in the metaphysis must be differentiated from a solitary bone cyst; this usually expands the cortex. If the lesion is in the diaphysis, Ewing's tumor must be considered. Other solitary lesions to consider in the differential diagnosis include osteomyelitis and tuberculosis and syphilis of the bone. Multiple lesions simulate multiple myeloma, metastatic bone tumors (neuroblastoma and lymphoma), Hand-Schüller-Christian's disease and osteitis fibrosa cystica.

In our case Ewing's tumor was considered in the differential diagnosis. Ewing's tumor usually causes more pain than eosinophilic granuloma, but in the case presented there was considerable pain. Periosteal bone formation is also more pronounced in Ewing's tumor. Since the prognosis of Ewing's tumor is very poor and its treatment radical, such as extensive irradiation or disarticulation, it is important to establish a correct diagnosis. The only way to do this is by biopsy of the lesion.

The presence of large mononuclear histiocytes or "foam" cells seen microscopically in eosinophilic granuloma has led to much speculation as to its relationship to Letterer-Siwe and Hand-Schüller-Christian's disease.[6] Histologically, the bone lesions of these two conditions are very much like those of eosinophilic granuloma. It has been thought that these three conditions may be the result of the same unknown infectious process, eosinophilic granuloma being the most benign and localized form, being limited to the skeleton.

Letterer-Siwe's disease, which runs a rapid, febrile course, is seen in children and is characterized by hepatosplenomegaly, generalized lymphadenopathy, anemia, purpura and bone lesions.[7]

Hand-Schüller-Christian's disease is a more protracted illness and in typical cases presents the triad of exophthalmos, bony defects of the skull and diabetes insipidus.

The relation of these two diseases to eosinophilic granuloma is based on microscopic findings. They may well represent variations in degree of the same basic process. Certainly there is no clinical alliance, since eosinophilic granuloma attacks only the skeleton and is benign.

7. Gross, P., and Jacox, H.: Am. J. M. Sc. **203**: 693, 1942.

SUMMARY

Eosinophilic granuloma is a benign bone lesion seen principally in young males. Pathologically, it is distinguished by the presence of large mononuclear cells. Eosinophils may or may not be present, depending on the age of the lesion. Clinically, pain, swelling and tenderness are noted. The diagnosis is made by biopsy, which is necessary to distinguish it from neoplastic lesions. Lesions may heal spontaneously or following curettage or small doses of radiation. The prognosis is excellent.

HUMAN COCCIDIOSIS

R. M. KISKADDON, M.D., AND R. J. F. RENSHAW, M.D.
CLEVELAND

Human infection with the intestinal protozoan Coccidium[1] is rare. Magath[2] reviewed 208 authenticated cases, approximately three fourths of which were found during World War I among soldiers in the eastern Mediterranean, and an additional 25 cases have been recorded to date.

Although infection usually does not give rise to symptoms, reports in the literature mention diarrhea, abdominal pain, lassitude and slight weight loss in association with coccidiosis. In contrast to the hemosporidia, the malarial parasites, coccidia of the human bowel, Eimeria and Isospora have not been proved pathogenic for man, although Priest[3] assumes cell destruction and invasion of intestinal epithelium by Isospora. The organism has never been found in intestinal tissue, and no specific lesion has been demonstrated. Many therapeutic agents have been used, including bismuth, iodide, quinine, gentian violet, emetine, anthelmintics and others without conclusive evidence of results.

The oocyst, the stage of development usually seen in fresh stool specimens, is ovoid, with a doubly refractile, smooth wall. One pole is smoothly rounded while the other is slightly truncated. The size varies from 21.75 to 40 microns in length and from 10 to 19 microns in width. When first passed it contains granular protoplasm with a clear space at each pole. This central mass divides into eight sporozoites.

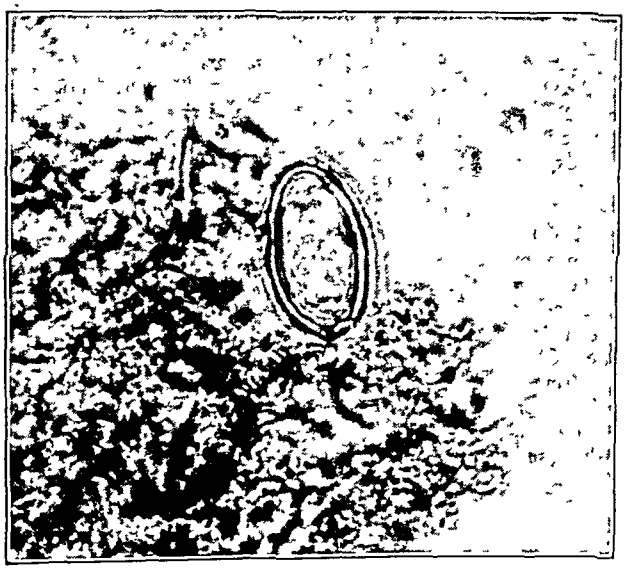
Because of the rare occurrence of this organism in man, the following case of Isospora hominis infection coincidental with or superimposed on a chronic ulcerative colitis is reported:

REPORT OF CASE

A man aged 60 was admitted to the hospital because of incontinence of feces and chronic cough of six months' duration. He often passed flatus, frequently had a burning sensation at the anus and occasionally noted blood in the stools. There had been no abdominal pain or weight loss. The patient was carefully questioned about his contact with animals, since coccidia are commonly found in certain animals. He liked to hunt and handled game frequently. His last contact with game occurred seven months previously, when he dressed rabbits, a dozen squab and a few squirrels.

On examination the patient had a temperature of 100.2 F., pulse rate of 88 per minute, systolic blood pressure of 176 and diastolic pressure of 110 mm. of mercury. The liver was slightly tender and enlarged to 1.5 cm. below the right costochondral margin. The edge of the liver was sharp, and there were no nodules.

Roentgenologic examination revealed a slightly enlarged heart, and electrocardiographic changes were consistent with left ventricular preponderance, myocardial damage and intraventricular block. With a barium meal gastrointestinal roentgenologic examination showed a normal esophagus, stomach and duodenum. After introduction of a barium enema a few diverticula in the sigmoid colon were demonstrated, the rest of the



From the Cleveland Clinic.

1. Coccidiosis is not to be confused with coccidioidomycosis, an entirely different entity caused by Coccidioides immitis.

3. Priest, R.: Case of Human Coccidiosis, J. Roy. Army M. Corps **68**: 317-319 (May) 1937.

colon being normal. The blood examination showed a severe secondary anemia with 4,200,000 erythrocytes and 47 per cent hemoglobin (7 Gm. with the Haden-Hausser hemoglobinometer), a leukocyte count of 8,950 and a corrected erythrocyte sedimentation rate of 0.68 mm. per minute. By the method used the rate is normal up to 0.45 mm. per minute. Consultation with an otolaryngologist confirmed a diagnosis of tracheitis.

Rectal examination revealed external hemorrhoids and poor anal sphincter tone. Proctoscopy for a distance of 25 cm. disclosed a granular, acutely inflamed mucosa, which bled on the slightest trauma but was devoid of ulceration. It had the appearance of Keefer's grade 2 chronic ulcerative colitis in an acute exacerbation.

Cysts of Isospora hominis were recognized [4] in a stool specimen. The parasite had an oval, smooth, doubly refractile wall and a central mass of granular protoplasm enclosed in an inner doubly refractile wall. The average size was about 10 by 7 microns. In some of the parasites, two or three round bodies were observed in the granular substance with no regularity of localization. Specimens were kept at 20 C., at room temperature, in a charcoal suspension and in an acid medium as suggested by Pons.[5] Although the organism was carefully and frequently observed for days and months after isolation from the stool, no division of the central body into sporoblasts was

Cyst of Isospora hominis (magnified) showing oval, smooth, doubly refractile wall and a central mass of granular protoplasm enclosed in an inner doubly refractile wall.

seen, and the small round bodies in the granular substance did not undergo change. The photomicrograph represents the parasite in the only form observed during a four months period.

During the patient's stay in the hospital stools were examined daily. A progressively decreasing number of coccidial cysts were observed, and none could be found after the seventh day. On the fourth day an attempt was made to recover the protozoa from the upper intestinal tract by duodenal drainage, but none were obtained. After the seventh day treatment for ulcerative colitis was instituted: 2 Gm. of succinylsulfathiazole in 200 cc. of water as a retention enema twice daily, three 500 cc. whole blood transfusions, ferrous sulfate and polyvitamin mixtures orally and crude liver extract intramuscularly.

On the eighteenth day proctoscopy revealed slight improvement in the appearance of the rectosigmoid mucosa. Blood studies revealed 6,000,000 erythrocytes and 78 per cent hemoglobin, with a color index of 0.65 and a volume index of 0.80. The erythrocyte sedimentation rate was normal. The tracheitis had completely subsided.

After discharge the patient continued the succinylsulfathiazole retention enemas, alternating ten days of treatment with seven days of rest. He was seen on the forty-fourth and again on the one hundredth day after hospital admission, and he reported much symptomatic improvement. He had three to nine stools every twenty-four hours, with only rare gross blood or pus. On both occasions proctoscopy revealed no further change. Examination of the stools showed a few epithelial cells and slight amounts of pus and occult blood but no coccidia. Three subsequent stool examinations between the one hundred and thirtieth and the one hundred and fiftieth days showed no coccidia.

COMMENT

Because division of the granular cytoplasm into sporoblasts and sporozoites was not observed in this case, there is some question whether the organism was a variant of Isospora hominis. There is also some question whether the organism was a sporocyst, because the average size (10 by 7 microns) compares favorably with the average size at the sporocystic stage (13 by 9.5 microns) reported by Magath.[2] We believe that the parasite in this case was a degenerate oocyst or a sporocyst of Isospora hominis.

It is of interest to note that the patient had a large tender liver. Stitt [6] mentions 5 cases of liver infection in men, and it is known that coccidia produce liver abscesses in animals. However, the result of the sulfobromophthalein liver function test was normal in this patient.

SUMMARY

A rare case of human coccidiosis superimposed on an ulcerative colitis was encountered. The only organisms isolated in this case were cysts of Isospora hominis. The infection cleared spontaneously with no specific treatment other than that for the ulcerative colitis.

Euclid Avenue at Ninety-Third Street, Cleveland 6.

4. The cysts were first recognized by Mr. Alfred Reich, chief technician of our laboratories. Dr. William S. Bray of the University of Virginia studied specimens and expressed the opinion that the cysts were atypical but were coccidia of the Isospora group.

FATALITY ASSOCIATED WITH THE ADMINISTRATION OF AMINO ACID DIGEST

A. R. Curreri, M.D.; O. V. Hibma, M.D., and P. P. Cohen, Ph D., M.D.
Madison, Wis.

The more recent literature on the parenteral administration of amino acid (protein digests) reveals that only occasionally are mild to moderate reactions encountered. Furthermore, it has been demonstrated that these reactions will subside either on reduction of the rate of flow of the infusion or on discontinuance of its administration. Our experience at the Wisconsin General Hospital with approximately two thousand parenteral administrations of amino acids has been similar to that of other investigators. Recently, however, 1 of our patients developed a severe and bizarre reaction which terminated in death. Since, to our knowledge, no mortality has been previously recorded with the use of amino acids, we present this case.

REPORT OF CASE

A white man aged 39, admitted for herniorrhaphy, presented no pertinent symptoms or signs other than those associated with right indirect inguinal hernia. Laboratory studies of the urine and blood were within normal limits. Hemoglobin was 17.7 Gm. The serologic reaction was negative. In view of the normal findings, this patient was selected for nitrogen balance studies. Accordingly, he was placed on a daily feeding program which consisted of the following: orally, 1,200 cc of orange juice whose nitrogen and carbohydrate content was known; parenterally, 1,000 cc. of 7.5 per cent glucose followed by 1,500 cc. of a mixture containing 5 per cent amino acids and 5 per cent glucose. An indwelling catheter was inserted into the urinary bladder to insure complete collection of the urinary output.

The first two days were uneventful. On the third day the patient developed a chill, headache, emesis and a fever of

6. Stitt, E. R.; Clough, P. W., and Clough, M. C.: Practical Bacteriology, Haematology and Animal Parasitology, ed. 9, Philadelphia, P. Blakiston's Son & Co., 1938, p. 440.

From the Departments of Surgery and Medicine, University of Wisconsin Medical School.

101 F. after 150 cc. of amino acids had been given. He was seen immediately, but the observer felt that we were dealing either with a moderate reaction or with an early cystitis. Nevertheless the fluids were discontinued, but unfortunately the remaining fluids were discarded by the nurse. Within three hours the temperature rose to 106 F., the blood pressure became imperceptible, the pulse was rapid and thready, the body took on a dusky red color and the patient was quite agitated. The progress was one simulating hypothalamic hyperthermia, shocklike state and renal failure. Supportive treatment consisted of parenteral saline solution and glucose, adrenal cortex extract, epinephrine and tepid sponges. On two occasions he was given intracardiac epinephrine. The patient died forty hours after the onset of symptoms.

Postmortem studies performed by our pathology department revealed generalized congestion of all the organs. The heart showed a minute acute abscess of the epicardium. There was congestion of the spleen with hyperplasia of the red pulp and leukocytic infiltration. The liver showed slender hepatic cells, hepatitis and infiltration of portal canals with lymphocytes and occasional polymorphonuclear cells. Chronic and acute cystitis was present. On gross examination of the brain there was demonstrable congestion and dilatation of the vessels. Microscopically some of the dilated vessels contained leukocytic thrombi made up largely of primitive blood cells. Many microscopic areas of perivascular degeneration were present. In addition there were many areas of endothelial congestion and destruction in all organs. It was concluded that these changes were the result of toxic chemical damage.

COMMENT

In reviewing this case it is difficult to state unequivocally the exact cause of death. We can consider four factors: (1) the presence of pyrogens in the glucose solution or tubing, (2) the presence of antigens or pyrogens in the amino acid solution, (3) extreme sensitivity of the patient to the drug and (4) the possibility of bacterial contamination in a previously opened container of amino acid solution.

The Wisconsin General Hospital prepares all saline and glucose fluids for parenteral use in the surgical section. These solutions are utilized only over a twenty-four hour period. A check of the solutions prepared and used at the time of this unfortunate reaction failed to present any other reactions whatever, even though 100 or more liters is used daily. Consequently we feel that we can rule out the glucose solution or tubing as a possible cause for this reaction.

The question of reactions due to antigens or pyrogens in the amino acid solution had been thoroughly studied by many investigators. Early in the history of the preparation of this agent it was shown that incomplete breakdown of protein, presence of minimal amounts of pork pancreas and a low p_H of the solution could either singly or in combination produce reactions. At the present time, however, the manufacturers test every batch of solution for the presence of these antigens or pyrogens. Furthermore, in a conference with the manufacturers of this particular amino acid preparation we learned that a thorough investigation of their records showed neither a serious reaction nor fatality from amino acids made up at the same time as the one used in this case. We would also point to the fact that the picture presented by this patient differed remarkably from those seen in 1939-1940 when we saw antigenic and pyrogenic reactions to these solutions. In those instances the principal features were a sudden pronounced hyperthermia, chill, nausea and vomiting, which subsided over a period of hours. At no time did we observe an extreme shocklike picture associated with hyperthermia as noted in this case.

During the period that this patient received amino acids, it was noted that several liters of solution contained a precipitate of tyrosine crystals. Such solutions were discarded in keeping with the manufacturer's instructions. It is certain that no precipitation was present in the ill fated solution.

While on the subject of precipitation, we wish to emphasize that amino acids should not be used in combination with strongly alkaline solutions. This fact has a very definite and practical value today, when (1) considerable amounts of sulfonamides are given intravenously and (2) employment by hospitals of itinerant nurses who fail to use care either in the handling or in the administration of intravenous fluids. For example, one of our new nurses poured some amino acid digest into a flask containing approximately 50 cc. of sodium sulfadiazine and walked out of the room. Immediately the resulting solution precipitated and turned milky white, owing to the precipitation of sulfadiazine. Fortunately the infusion was quickly stopped by a resident who happened to be at hand. In all likelihood the incompatibility of this solution applies only when the ingredients are mixed outside the body.

As amino acid solutions represent excellent mediums for bacterial growth and since bacteria break down amino acids to toxic amines, the theory was advanced that a previously opened bottle was employed. It has been our policy, especially since the manufacturers specifically so advise on their bottle labels, never to reuse a bottle of amino acids once it has been opened. It was indeed unfortunate that the remaining solution in this reported case was discarded, because the results of bacterial and chemical studies would have aided immeasurably in determining the cause of death.

This case was a rather bitter experience for us. Nevertheless we feel that the parenteral use of amino acids has a very definite place in the treatment of debilitated patients who cannot take foods orally. Sufficient evidence is now at hand to show the superiority of wound healing and more rapid convalescence when a positive nitrogen balance is maintained. If this reaction which resulted in death were to be the sole cause in deterring the use of this valuable adjunct, then blood transfusions, vitamins and most of our valuable drugs should be deleted from our medical armamentarium, since one or more deaths have resulted from their application. At the same time we definitely feel that these amino acids should be used with care, and that probably some one on the hospital staff should assume responsibility for (1) clearness of amino acid solution, (2) slow rate of administration, (3) certainty of *not mixing* amino acids with solutions of a high p_H and (4) discarding unused contents of a bottle once it has been opened.

Since we were unable to prove unequivocally that this death was due to the amino acids per se rather than to some extraneous factor or factors, we do not feel justified in stressing any additional potential dangers of parenteral amino acid administration other than those already known.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., *Secretary.*

RIBOFLAVIN (See New and Nonofficial Remedies, 1944, p. 613).

The following dosage form has been accepted:

PREMO PHARMACEUTICAL LABORATORIES, INC., NEW YORK

Tablets Riboflavin: 1 mg., 2 mg. and 5 mg.

PENICILLIN (See Supplement to New and Nonofficial Remedies, 1944, p. 18).

The following dosage form has been accepted:

BURROUGHS WELLCOME & CO., INC., NEW YORK

Penicillin Sodium: 100,000 Oxford unit bottles.

SYNTHETIC OLEOVITAMIN D (See New and Nonofficial Remedies, 1944, p. 623).

The following additional dosage form has been accepted:

MEAD JOHNSON & COMPANY, EVANSVILLE, IND.

Viosterol in Oil: 10 cc. bottles. Viosterol in corn oil.

THE ROLE OF ESTROGENS IN PHYSIOLOGIC HYPERPIGMENTATION

Davis and his associates [1] at the Lying-In Hospital of the University of Chicago administered diethylstilbestrol to a group of young women with primary amenorrhea after all other measures had failed. After starting administration of 1 mg. of diethylstilbestrol daily, these girls matured rapidly and their reproductive organs reached a normal state of development. The nipples, the areolas and the linea alba, it was noted, pigmented intensely. The degree of pigmentation far exceeded that seen during normal gestation. Administration of diethylstilbestrol to some 1,000 patients with menopausal complaints gave the usual satisfactory response, but the patients did not exhibit an increase in pigmentation in the usual localities, even though the total dosage of estrogens far exceeded the amount administered to the young girls with primary amenorrhea.

In an attempt to elucidate the mechanism of estrogenic pigmentation and the reason for the difference in response in primary amenorrhea and pregnancy, the investigators performed a number of animal experiments. Ten castrated young guinea pig males were injected every other day with 25 micrograms of diethylstilbestrol dissolved in 0.1 cc. of sesame oil. Five days after beginning, the animals began to show considerable pigmentation about the nipples. This pigmentation reached its maximum at the end of two weeks. A control group of animals in which sesame oil alone was injected did not develop pigmentation. Diethylstilbestrol applied locally to the nipple of a guinea pig likewise resulted in this phenomenon, indicating that the action of estrogens on the melanoblast cells in mammals is a direct one. A group of animals given 25 micrograms of diethylstilbestrol and 75 international units or 0.1 cc. of chorionic gonadotropin failed to display the phenomenon of estrogen induced pigmentation. Inhibition of pigmentation in this set of experiments is probably the result of chorionic cell activity. Pigmentation of pregnancy and artificially induced pigmentation by estrogens are both dependent on a pituitary-gonadal relationship. In this relationship estrogens can replace the absent or ineffective gonad when the anterior lobe of the pituitary is functioning normally. In these experiments neither prolactin, progesterone nor the adrenals appeared to play a role in the pigmentation. In pregnancy the increased amount of estrogenic substances present in the body predisposes to hyperpigmentation of the nipples, the areolas and the linea alba as well as to the characteristic deposition of pigment on the face with the production of the typical "mask of pregnancy." The hyperpigmentation is always limited to areas naturally containing pigment. The experiments confirm the role of the estrogens in physiologic hyperpigmentation. The hyperpigmentation observed in the young women treated with estrogens probably develops as a result of the establishment of a normal pituitary-gonadal relationship by the substitution of estrogens for the absent ovarian function. The authors suggest that a good pigmentary response in these young women is diagnostic of primary ovarian failure in the presence of a normal pituitary gland. The absence of hyperpigmentation in women treated with estrogens after the menopause is probably due to the anatomic and the functional changes of the anterior lobe of the pituitary gland.

Thus it appears that there are real differences between the pituitary-ovarian relationships in primary ovarian failure, pregnancy and the postmenopausal period.

MILK SICKNESS: A RETROSPECT

In an address before the Filson Club in Louisville, Ky., Philip D. Jordan [1] of Miami University, Oxford, Ohio, reviewed a valuable chapter in medical history of pioneer days in this country. The once mysterious "milk sickness" for over a hundred years was a scourge among many endemic ills which beset early settlers throughout the Middle West. It affected cattle and man alike. Little was written about it before the great period of colonization in the first half of the nineteenth century. The disease was variously designated as swamp sickness, tires, distemper or trembles. First heard of in Virginia and on the upper Ohio, it soon became common enough in Tennessee, Kentucky, Indiana and the Illinois country.

The symptoms, always incident to the drinking of milk, were dizziness, increasing lassitude, loss of appetite, nausea followed by vomiting, constipation, subnormal temperature, intense thirst and the odor of acetone. This condition in severe cases would develop into a typhus-like appearance with difficult breathing, pros-

1. Jordan, P. D.: Milk Sickness in Kentucky and the Western Country, Filson Club Historical Quarterly 19: 21 (Jan.) 1945.

tration and coma. The death rate was from 10 to 25 per cent.

Early medical literature teems with references to this disease. Early settlers feared it so greatly that they would carefully avoid any region where it appeared frequently. One such place was in southern Indiana, where Nancy Hanks Lincoln was known to have died of it in 1819. Low and swampy localities seemed to favor the prevalence.

The settlers knew that the illness was induced by the drinking of milk. They surmised that its cause might be a poison derived from some venomous substance or plant eaten by the cows. About 1840 the great pioneer physician Daniel Drake undertook a long journey into the Ohio country to trace the cause of the poison. His colleagues variously accused species of Rhus, or Bignonia, but in 1838 John Rowe, a farmer, announced publicly that the white snakeroot (Eupatorium ageratoides, or urticaefolium) was the plant which caused the trembles in cattle and man. This statement was not credited by Drake, and its truth was not recognized until 1917, seventy-nine years later.

The prognosis generally was none too good. Opium, hydrotherapy, blistering and calomel in large doses, whisky, bismuth, charcoal and lobelia tincture were tried, also sodium and potassium bicarbonate. As late as 1937-1938 21 cases occurred in Illinois, with a mortality rate of 10 per cent.

The suspicion gradually centered on the snakeroot (W. J. Vermilya, 1858; N. S. Townshead, 1873) and in 1906 E. L. Moseley showed that snakeroot fed to animals in the laboratory will produce "trembles." E. O. Jordan and his associates in 1908 isolated a bacillus (Bacillus lactimorbi) which would be subject of suspicion, but they did not assert that it was the causative agent. Finally, in 1917 the U. S. Bureau of Animal Industry announced that a poisonous substance, tremetol, had been isolated from the white snakeroot; others confirmed this discovery, and a treatment (saline purgation, fluids, alkalis by mouth, glucose intravenously, enemas, honey and whisky) was devised. Still a specific antidote for tremetol has not thus far been discovered.

The problem of the etiology seems simple, but the careful investigator knows that it only seems so. Cattle feed on hundreds of herbs still not analyzed. The "trembles" presents a mutable picture not uncommon to many intestinal infections or endemic troubles where in earlier days calomel, bleeding or opium was indicated by symptoms. Finally, many poisons show such a variation of the clinical picture that the presence of an unknown substance would confuse even the most experienced practitioner. But as Eupatorium ageratoides still grows in our soil, and as the rayless goldenrod of the Southwest also contains tremetol and causes the trembles, milk sickness may well remain in the textbooks.

MENTAL DECLINE AND ITS RETARDATION

The human life span has been extended from something like 29.4 years for the ancient Greeks to 59.3 for men and 62.8 for women in the United States of America. The number of people over 65 now reach the grand total of 9 million; statisticians anticipate 26 million past 65 in 1980. Thus the question of retardation of mental decline assumes great practical significance. George Lawton [1] of the Old Age Counseling Center, New York, points out that not all of the physical inadequacies of older persons are due to inescapable infirmities of old age. Much results from neglect of physical condition and failure to continue exercise. We gain mental stature quickly, particularly between 13 and 16 years, and lose it slowly. The ability to learn new facts reaches its maximum in the late teens and early twenties and then starts slowly declining. While there is a decrease in the amount of learning which persons acquire as they grow older, exceptional minds possess the ability to renew themselves continually and to exploit to the fullest their intellectual resources. Even ordinary persons have far more ability and learning capacity than they utilize. Part of the ostensible mental loss of older persons is simply the cumulative effect of poor habits of work. From the point of view of the best interests of most older persons, a regular job is necessary and desirable. Lawton believes that retirement is inadvisable for many types of persons.

Many a man or woman thinks creatively and makes invaluable contributions at age levels far beyond early youth. Lawton stresses that it is fear of aging, rather than the aging process itself, which often causes a functional loss in the mental realm, just as it does in the physical. Admitting the inevitable deterioration of our abilities with advancing age, it would be well to remember, as Lawton points out, that every handicap has two aspects. One is the handicap itself. The other is the way the handicap is used.

It is generally conceded that the higher the original intellectual endowment, the slighter the decline. Judgment, better integration of knowledge, practice over a long period of years will compensate for losses in motor dexterity and sensory acuity of the young. Indiscriminate and arbitrary shelving of men and women merely for age results in great loss to society and the individual. Based on his own experience, Lawton believes that retirement on pension, medical care and old age homes will not solve the problem of the older person. Rather he sees the necessity of schools for the aged, recreation centers, arts and crafts centers, sheltered workshops, adult playgrounds, marriage brokers and social clubs. Occupational therapy holds great

1. Lawton, George: Mental Decline and Its Retardation, J. Gen. Psychiat. 32:239 (April) 1945.

possibilities in the program of aiding the aged. Recent studies in geriatrics suggest that the medical profession is interested in the problems of the aged and that much constructive work is going to result from such studies.

Current Comment

POSTGRADUATE COURSES FOR VETERANS AND CIVILIAN PHYSICIANS

On page 751 of this issue of THE JOURNAL the Council on Medical Education and Hospitals of the American Medical Association presents its semiannual compilation of postgraduate continuation courses being offered in a wide variety of fields in the various medical educational institutions of this country. This list includes courses offered for the period of July 1, 1945 to Jan. 15, 1946. Before the expiration of this period another listing will be published. The present compilation is especially important and timely. It includes a number of courses which have been designed primarily to meet the needs of returning physician veterans. Already a large number of educational institutions are planning to meet such demands. Therefore the list has become considerably larger than any previous compilation. The variety of subjects covered is especially extensive, and the geographic distribution of the institutions offering this work is wide. It is hoped that the list will continue to grow as more institutions formulate definite plans for returning medical officers and that this and subsequent listings will become increasingly useful, especially to returning physicians who desire review and refresher courses.

VIVISECTION EXHIBITIONISM

Dr. Franklin Bliss Snyder, president of Northwestern University, Dr. George A. Gardner, acting dean of the Medical School, and Dr. Andrew C. Ivy of the physiology department, charged with cruelty to animals by Mrs. Grace Petkus, vice president of the Animal Welfare League, aided and abetted by Mrs. Irene Castle McLaughlin, were recently tried in a Chicago municipal court. After the testimony was heard, the judge dismissed the case. Reporters recognized the incident as merely another of the episodes involving the ex-actress and terpsichorean who seems to hanker continuously for the limelight and plaudits which once were hers. Said the Chicago *Sun*, in the issue of June 29, "That old courtroom drama, which might be called 'The Vivisection Blues' and which has played more return engagements here than 'Rose Marie,' was on the boards again yesterday, this time in the Chicago Avenue Court before Judge John R. McSweeney. Mrs. Irene Castle McLaughlin appeared again as the emotional chief witness, a role she created years ago, for medical science and against Hearst's Chicago *Herald-American*, which for a decade or so has been the play's angel. It was the consensus afterward that unless a happier ending can be achieved 'The Vivisection Blues' never can be taken on the road." The Chicago *Tribune* featured Mrs. McLaughlin's costume. The Chicago *Times* said "Irene's crying act leaves court cold" and in a semifacetious manner emphasized Mrs. McLaughlin's clothes. The *Daily News* just noticed the incident, but the Hearst *Herald-American* devoted a column on page 7 to saying "We haven't begun to fight." Inadvertently, Mrs. McLaughlin disclosed the real issue. "Well," she is reported to have remarked, "we got a university president in court for the first time, anyway." The antivivisectionists' purpose then is not the protection of animals but the heckling of scientists and, perhaps most important, getting their names and their pictures in the paper. We have seen la belle Castle's summer outfit; by next fall she will be ready no doubt to exhibit something special in furs from small animals trapped in the woods.

PENICILLIN VARIATIONS

After the discovery of penicillin and the rapidly expanded commercial production which made it readily available, a vast literature accumulated concerning the effects of this therapeutic agent on the course of many diseases. Some variations have been observed between the British and American products, particularly when the single dose technic is used. Recently an explanation for the variations [1] stressed the fact that a partitioning of the active components occurs in the course of isolation of penicillin from the Penicillium notatum cultures. The product obtained by growth in open flasks is called penicillin F or penicillin I by the British, while that produced by the tank method is called penicillin G or II. There is also a product designated penicillin X, III or allopenicillin. Since penicillin production by the tank-submerged cultures gives the greatest yield, this type of product is in most common therapeutic use; it is almost exclusively the G type penicillin. Evidence suggests that each fraction has therapeutic specificity. In the case of the gonococcus this is most striking; here the G fraction is less active than the crude penicillin, and the X fraction is more active than either of the previous two. However, the content of each fraction present in a single ampule is not known, since fractional assaying has not been considered practical up to the present. The various penicillins vary in proportion not only according to different methods of production but also from one batch of the drug to another produced by the same method. It is obvious that until penicillin can be produced in a chemically pure form the recognition of its variable complex nature should be considered in any attempt to evaluate its action against disease producing agents.

MEDICINE AND THE WAR

ARMY

PROMOTIONS IN THE ARMY MEDICAL DEPARTMENT

The following promotions to the rank of brigadier general (temporary) were recently announced by the War Department:

Brig. Gen. Larry B. McAfee, as assistant to the Surgeon General of the Army, is serving as commanding general of Bruns General Hospital, Santa Fe, N. M.

Brig. Gen. Addison D. Davis, as assistant to the Surgeon General of the Army, is serving as commanding general, Carlisle Barracks, Pa., and as commandant of the Medical Field Service School.

Brig. Gen. George W. Rice, surgeon of an army in the Southwest Pacific Area since September 1944.

Brig. Gen. Edward Reynolds, as Chief, Supply Service, Office of the Surgeon General since May 1944. General Reynolds is charged with the procurement, storage and issue of all medical, dental and veterinary supplies for the Army.

Brig. Gen. Charles M. Walson has been Surgeon, Second Service Command, Governors Island, New York, since January 1944.

Brig. Gen. Elliott C. Cutler has been Chief Consultant in Surgery, Headquarters, European Theater, since July 1942.

MORE VETERINARIANS NEEDED

The director of economics stabilization recently directed that immediate steps be taken to bring larger numbers of nonfederally inspected meat producing establishments under federal inspection in order to meet the huge requirements of the armed forces. In line with this directive, several teams have been sent into the field to survey several hundred of these noninspected plants which it is believed can be made to qualify for limited federal inspection. Under agreement between the war food administrator and the secretary of war, signed in February 1944, when the Department of Agriculture cannot supply the inspection at plants brought under federal supervision, in order to contribute to military meat requirements, the inspection service is furnished by the Veterinary Corps. It is anticipated that as a result of the drive now being made to bring under inspection more plants, approximately 150 additional veterinary officers will be required for the program. Accordingly, a recommendation has been submitted to the War Department to raise the ceiling for Veterinary Corps officers to provide for this additional requirement in order to maintain health standards.

262d MEDICAL BATTALION AWARDED PLAQUE

The 262d Medical Battalion, now in action in the Philippines, recently received the Meritorious Service Plaque. The award was made by Gen. Walter Krueger, commanding general of the Sixth Army, who cited the battalion's high standard of efficiency in clearing and evacuating casualties on Leyte Island. The battalion is the third unit of the 2d Engineer Special Brigade to receive the Meritorious Service Plaque. The 262d Medical Battalion is commanded by Lieut. Col. A. E. Rosen, who has been with the unit since its organization at Cape Cod in June 1942.

BRONZE STAR MEDAL

Sgt. Carl E. Stuart, Medical Department, Walthill, Neb., was recently awarded the Bronze Star for his work among the American prisoners in the Philippines. While a prisoner of war he was wardmaster and hospital attendant from November 1943 to January 1945, caring for other American prisoners in the tuberculosis ward of Japanese Prison Camp Number One, Cabanatuan, Philippine Islands. Working under the most hazardous and primitive conditions with a minimum of protection from disease, he gave cheerful, untiring care to his patients even though subjected to constant interference and abuse from Japanese guards and while suffering himself from the ravages of prison life. Improvising equipment and laboring countless hours, he did his utmost for critically ill patients. On the arrival of an American liberation force he continued to care for his patients until all had been removed to friendly lines and he was convinced that medical facilities were available. Only then did he seek treatment for himself. His determined efforts, his loyalty to his suffering comrades and his inspiring conviction that the Japanese yoke would be lifted instilled in many desperately ill captives the will to live through their terrible ordeal.

FRONT LINE MEDICAL CARE SUCCESSFUL

Brig. Gen. Hugh J. Morgan, chief consultant in medicine, Office of the Surgeon General, U. S. Army, who recently returned from a nine week, 15,000 mile tour of the European and Mediterranean theaters of operation, reports that the Army's policy of moving medical care, as well as surgical care, nearer and nearer to the front lines has proved eminently successful.

The primary task of the medical corps is to keep soldiers on active duty, and this is especially vital in combat areas, where regiments, divisions and whole army groups function as a team, with each unit doing its special task. The quality of medical care given in operations areas which General Morgan visited is extraordinarily good, he said. There is the same supervision of all cases by specialists in specific fields of medicine as there is in the United States.

58th EVACUATION HOSPITAL

The 58th Evacuation Hospital, commanded by Col. Charles E. Spellman, formerly of Missoula, Mont., has averaged as many as a thousand cases weekly over a three week period. With a normal bed capacity of 400, the unit found facilities during the heaviest fighting on Cebu to accommodate and care for as many as 800 patients. After serving for more than a year at Camp Carson, Colorado, where it was originally activated, the 58th Evacuation Hospital went into actual operation on a small jungled island in the Admiralty group on March 6, 1944, and with the invasion of the Philippines, Colonel Spellman and his veteran crew set up shop in muddy Tacloban, capital of Leyte. Then followed the setting up of temporary bivouac near the cathedral town of Pardo, and in a few days the 58th followed the American division into the smoking ruins of Cebu City.

NUTRITION SURVEY COMPLETED

Major Marvin B. Corlette, chief, Civilian Nutrition Branch, Nutrition Division, Preventive Medicine Service, recently returned from a seven weeks tour in the European theater, where he was in charge of a nutrition survey team which worked primarily in the Netherlands. This team was with the first troops into Utrecht, Amsterdam, The Hague and Rotterdam after the German surrender. Major Corlette also made brief nutrition surveys in Belgium and Germany and visited the concentration camps at Belsen and Dachau, Germany, where he assisted in formulating plans for feeding starvation cases.

COLONEL SHULL GETS NEW ASSIGNMENT

Following a tour of duty in the Office of the Surgeon General of more than three years, Lieut. Col. Harrison J. Shull, M. C., departed from that office for his new assignment as consultant in medicine to the Sixth Army, in the Southwest Pacific.

Colonel Shull's successor as chief of the General Medicine Branch of the Medical Consultants Division is Major Frederick T. Billings, M. C., recently returned from overseas, where he was assigned to the Medical Service of the 118th General Hospital and also served on temporary duty as a consultant in medicine.

NEW APPOINTMENT

Lieut. Col. Fred E. Ball, formerly of Chicago, has been appointed District Consultant for Internal Medicine to the Air Surgeon. Now chief of Medical Services at the AAF Regional and Convalescent Hospital, Miami District, Colonel Ball is consultant for the Southeast District, which comprises the states of Tennessee, Mississippi, Alabama, South Carolina, Georgia and Florida. Dr. Ball graduated from the University of Minnesota Medical School, Minneapolis, in 1923 and entered the service in 1942.

AWARD OF MERITORIOUS SERVICE UNIT PLAQUE

The 45th Evacuation Hospital (Sm.) was recently awarded the Meritorious Service Unit Plaque "for superior performance of duty in the accomplishment of exceptionally difficult tasks during Dec. 2, 1944 to Feb. 16, 1945."

ARMY AWARDS AND COMMENDATIONS

Colonel Charles B. Odom

Col. Charles B. Odom, formerly of New Orleans, was recently awarded the Bronze Star. The citation accompanying the award read "for heroic achievement in connection with military operations against an enemy of the United States in Germany. On April 6, 1945 Colonel Odom, assistant surgeon, Headquarters Third U. S. Army, voluntarily undertook a daring mission behind enemy lines to give medical aid to wounded allied prisoners held in a prisoner of war camp at Hammelburg, Germany. Traveling at night by quarter-ton truck, braving enemy sniper and mortar fire and the constant threat of ambush, he reached the camp successfully and aided a Serbian medical officer in treating the wounded. The courage and skill and loyal devotion to duty Colonel Odom displayed are in keeping with the highest traditions of the military service." Dr. Odom graduated from Tulane University of Louisiana School of Medicine, New Orleans, in 1932 and entered the service July 15, 1942.

Captain R. Hills McArthur Jr.

The Soldier Medal was recently awarded to Capt. R. Hills McArthur Jr., formerly of Clio, Mich. According to the citation accompanying the award "The pilot had attempted to land his aircraft after a dive bombing mission with four phosphorus bombs still attached to the plane. At the first impact of landing one bomb exploded under the tail surfaces of the plane and caused the aircraft to turn over on its back and immediately to catch fire. Captain McArthur rushed to the scene of the accident and without regard for the hazards of pools of gasoline and oil, or to the danger of explosion of remaining bombs, which were emitting smoke, succeeded in removing the canopy. Then, by lying on his back in gasoline and oil and working under the most difficult conditions, Captain McArthur freed the pilot from his harness and parachute and carried him to safety." Dr. McArthur graduated from the University of Tennessee College of Medicine, Memphis, in 1937 and entered the service July 8, 1942.

Lieutenant Colonel Roy D. Arn

The Bronze Star was recently awarded to Lieut. Col. Roy D. Arn, formerly of Dayton, Ohio. The citation reads, in part, "Lieutenant Colonel Arn volunteered for temporary duty in support of a front line unit despite the fact that such duty was not commensurate with his rank, age or assignment to a fixed base hospital. He found the unit after an arduous and dangerous three day trip on foot over the most rigorous mountain terrain and immediately undertook the performance of major surgical procedures which resulted in the saving of many lives. He continued to render his services until the unit finished the combat operation. The enthusiasm manifested by Lieutenant Colonel Arn in volunteering for such an assignment and in the performance of fine surgical procedures which saved the lives of many men reflects great credit on himself and the service." Dr. Arn graduated from the University of Michigan Medical School, Ann Arbor, in 1926 and entered the service May 9, 1942.

Major Thomas Floyd Jr.

Major Thomas Floyd Jr., formerly of Abbeville, Ala., was recently awarded the Bronze Star "for outstanding professional services from June 6, 1944 to January 1945," when he served as a surgeon with the Army Medical Corps under combat conditions. Major Floyd's surgical team performed major operations on 1,040 casualties during this six months period Attached to a First Engineer Special Brigade, Major Floyd is member of a medical battalion that has been overseas twenty-seven months. He is stationed at a forward field hospital of the First Army, and his was the first army surgical team to operate east of the Rhine, at the Remagen Bridgehead. Dr. Floyd graduated from Tulane University of Louisiana School of Medicine, New Orleans, in 1907 and entered the service in September 1942.

Lieutenant Colonel Isidore A. Feder

The Bronze Star was recently awarded to Lieut. Col. Isidore A. Feder, formerly of Brooklyn, "for meritorious service in connection with military operations against the enemy as chief of medical service, 45th Evacuation Hospital, Semimobile, from June 17, 1944 to Aug. 1, 1944 in France. Lieutenant Colonel Feder expertly supervised the diagnosis and treatment of numerous medical cases. He displayed keen insight in properly distributing the medical services of officers, nurses and enlisted personnel to insure prompt and adequate treatment of the wounded. By his initative, professional knowledge and skill, Lieutenant Colonel Feder reflected credit on himself and on the military service." Dr. Feder graduated from Tufts College Medical School, Boston, in 1927 and entered the service Aug. 12, 1942.

Major Allen M. Boyden

Major Allen M. Boyden, formerly of Astoria, Ore., was recently awarded the Bronze Star for "meritorious service as Surgeon, Surgical Team 1, 3d Auxiliary Surgical Group. Arriving on the fire-swept invasion beach of Normandy on D day, Major Boyden immediately undertook his medical tasks. Despite a heavy flow of casualties he calmly and efficiently supervised the treatment of many wounded soldiers, although frequently subjected to enemy artillery and aerial bombardment. During subsequent operations on the continent he consistently performed his assignment in an outstanding manner. By his surgical skill and untiring efforts he set an example worthy of emulation." Dr. Boyden graduated from the University of Michigan Medical School, Ann Arbor, in 1932 and entered the service Oct. 27, 1942. He is now in Germany caring for prisoners and refugees from the notorious German camps.

Captain Nelson M. Black Jr.

The Soldier's Medal was recently awarded to Capt. Nelson M. Black Jr., formerly of Iowa City, "for outstanding heroism displayed at Army Air Base, APO 215, on Dec. 24, 1944. Immediately following the crash of a B-29 type aircraft loaded with bombs, Captain Black rushed to the scene and unhesitatingly faced the danger of the exploding ammunition, incendiary bombs and oxygen tanks, to exert his every effort in finding and rescuing the bodies of the dead and injured crew members from the blazing wreckage. This deed was performed at extreme risk of life, since, in addition to the other attendant dangers, many 500 pound demolition bombs on the verge of explosion from the excessive heat were in the area. The actions of Captain Black in the face of great danger were instrumental in saving the lives of several crew members and were a source of courage to other personnel comprising the rescue party. Such disregard for his personal safety in the execution of an act of courage reflects the highest credit on Captain Black and the Army Air Forces." Dr. Black graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1939 and entered the service Aug. 12, 1942.

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

July 2, 1945.

Public Health Service Personnel Get Military Status

President Truman has by executive order given 3,000 U. S. Public Health Service members military status for the duration of the war. This action was taken under authority of the Public Health Service Act of 1944 and is effective July 21. The Public Health Service has no enlisted personnel, and its commissioned corps of around 3,000 includes physicians, dentists, sanitary engineers, pharmacists and other scientists and nurses. The President's order gives this personnel the same status, benefits, discipline and obligations of members of military establishments and provides uniformity in status and in discipline as between various members of the U. S. Public Health Service commissioned corps. Formerly some officers acquired veteran status while others did not, depending on their assignments. The order does not transfer administration of the Public Health Service either to the Army or to the Navy.

Curb Urged on Over Counter Sale of Sulfonamide Drugs

District of Columbia health officials have been asked to curb over the counter sale of sulfonamide drugs by the Committee on Public Health of the Medical Society of the District of Columbia, of which Dr. Edward J. Stieglitz is chairman. The committee also asked the District commissioners to assist District Health Officer Ruhland in effecting such restrictions if necessary. The committee endorsed the recommendations contained in the report of the subcommittee of the committee on public health relations of the New York Academy of Medicine, pointing out the dangers inherent in the use of the sulfonamide drugs. Editorially, the *Medical Annals of the District of Columbia* has expressed the hope that action on the committee recommendations, which was endorsed by the executive board, would be taken soon.

Hospital Center Critics Asked for Better Plan

With the Senate passed bill for a 1,500 bed medical center in the national capital delayed until completion of a Washington hospital survey in the fall, Senator Tydings, Democrat of Maryland, co-author of the measure, has challenged critics to come forth with a better plan. The bill is now before a subcommittee of the House District Committee. Budget Director Harold D. Smith urged delay until the survey and criticized managerial and financial plans for the new center. Said Senator Tydings "Simply to criticize the existing bill, without producing a better or less costly bill to improve or construct hospital facilities, is not helping the hospital situation of the District. In effect it is simply preventing any improvement to the crying needs for better and more modern hospitals and facilities to take care of the growing city."

One Third of Civilian Dentists in Armed Forces

Since 1940 one third of the civilian dentists of the country have gone into the armed services, it was testified before the subcommittee on health of the Senate Committee on Education and Labor. Illustrating the availability of dental care, it was reported that in California during 1940 there was 1 dentist for every 1,279 people, while South Carolina had 1 dentist for every 5,263. This information was disclosed at hearings on the proposal of Senator Murray of Montana to spend a million dollars to establish a National Institute of Dental Research and appropriate an additional $730,000 a year to keep it going. Senator Claude Pepper of Florida and Senator George T. Aiken of Vermont have jointly proposed that federal grants-in-aid be made to the states and local governments so that they can establish and maintain "adequate measures for the prevention, treatment and control of such [dental] diseases, including a dental care program for children, the training of personnel for state and local dental health work and the development and maintenance of effective means for the education of the public concerning dental disease." Dental neglect among children between the ages of 6 and 18 years is said to be such that only about 5,650,000 of the annual crop of 22,500,0000 decayed teeth are filled. The population over age 3 is said to have an accumulated need for 39,500,000 crowns and bridges, 20,000,000 partial dentures, 20,000,000 dental disease treatments and 125,000,000 prophylactic treatments.

Allied Surveillance of German Research Urged by Berge

Assistant Attorney General Wendell Berge told the subcommittee on war mobilization of the Committee on Military Affairs that allied authorities must exercise careful surveillance over German research programs. Pointing out that it was through research that Germany was able to prepare clandestinely for this war, he warned that German officials will endeavor to maintain the core of organized research personnel and technical facilities "on which their know-how depends." He said this war has demonstrated that the fields of major importance are synthetic chemistry, metallurgy, electronics and aerodynamics. When the war ended, he said, Germany was on the verge of developing "new and more terrible instruments of destruction, particularly in the field of long distance rockets and explosives."

Council on Medical Service and Public Relations

PREPAID MEDICAL CARE NEWS

Membership of Hospital Plan Enlarged

The Blue Cross Plan for Hospital Care showed the largest membership increase during 1944 of any year in its history on the enrolment of 163,039 subscribers, bringing the total membership to 747,317, in an announcement made by John R. Mannix of Chicago, executive director.

Medical Service Plan Corporation Authorized in Minnesota

During a meeting of the House of Delegates of the Minnesota State Medical Association at St. Paul on May 19 and 20 plans for creating a statewide voluntary nonprofit medical service corporation were authorized and set into motion.

Considerable discussion was given to the method of selecting the twenty-one incorporators to serve as the original board of directors of the corporation. In order to explain the provision for twenty-one incorporators Dr. A. W. Adson, chairman of the Committee on Medical Service, told the delegates that not only geographic representation of the profession was considered desirable but representation of various specialties as well. The arbitrary number of twenty-one was deemed necessary to provide both—two physicians from each councilor district plus three at large, the latter to be selected by the eighteen members representing the councilor districts.

Preparation of articles of incorporation and formulation of detailed plans after careful study of existing models of the various states were authorized.

The question of whether the Minnesota Medical Service plan will be coordinated with the Blue Cross, as in the case of Michigan, or whether some commercial sickness and accident insurance company will participate in the venture is a decision still to be made by the board of directors.

Bureau of Information

PROGRESS REPORT, JUNE 27, 1945

The progress of the Bureau of Information is not as rapid as is desired, but during recent weeks there has been a gratifying increase in the number of completed county summary sheets received from the state and county medical societies. This response is indicative of a whole-hearted effort on the part of the various societies to aid in the completion of this phase of the Bureau of Information.

The accompanying table gives the returns by county from each of the states as of June 27, 1945.

Summary Sheets Received from State and County Medical Societies

State	Number of Counties	Number of Counties Reported	Counties Unreported
County Returns Complete as of June 28, 1945			
Arizona	14	14	0
Arkansas	75	75	0
Connecticut	8	8	0
District of Columbia	1	1	0
Iowa	99	99	0
Kansas	105	105	0

Maine	16	0	16
Maryland	24	0	24
Mississippi	82	0	82
Oregon	36	0	36
Rhode Island	5	0	5
Vermont	14	0	14
Total	180	0	180
Total counties	3,073		
Counties reported	1,996		
Counties unreported	1,077		

A current knowledge of needs of communities for doctors is essential if adequate help is to be given veteran medical officers in their problems of medical practice. These needs can be indicated on the summary sheets under "Remarks" by the state and county secretaries and are then available to inquiring medical officers. Frequent reports from state and county medical societies about needs of communities for doctors will help maintain current files and will increase the service of the Bureau.

With the information available on a completely filled out summary sheet, it is readily possible for an interested medical officer to make an initial selection of areas in which he might like to practice. Since vacancies are held open in many communities for doctors now in military service, further investigation by direct correspondence with state and county medical societies will always be necessary to insure an accurate report of the needs of individual communities.

Medical Legislation

MEDICAL BILLS IN CONGRESS

Survey of Medical Personnel Needs

Under a resolution submitted by Senator Downey, California, S. Res. 134, the Senate Committee on Military Affairs would be directed to make a complete investigation with respect to the relative needs of the armed forces and the civilian population for services of medical personnel to ascertain (1) whether, as a result of developments in the war, or through more efficient utilization of medical personnel, such personnel can be released from the armed forces for civilian service without impairment of the war effort; (2) the speed with which demobilization of medical personnel of the armed forces can be accomplished as the needs of the armed forces diminish; and (3) whether any further action is necessary to insure an adequate supply of trained medical personnel to meet the future needs of the armed forces and the civilian population of the nation.

Social Security Act

Senator Green, Rhode Island, has introduced S. 1188 to amend and extend the provisions of the Social Security Act so as to provide, among other things, hospitalization benefits and benefits for disabled workers. So far as the hospitalization provisions are concerned they are similar to those that were included in the bill introduced in the 77th Congress by Congressman Eliot, Massachusetts, which was analyzed in THE JOURNAL, Sept. 26, 1942, page 296.

Veterans Administration

The appointment of an advisory committee by the President to advise him and the Administrator of Veterans' Affairs with respect to the formulation and administration of programs for providing hospitalization and medical care to veterans is proposed by S. 1187, introduced by Senator White, Maine, for Senator Shipstead, Minnesota. It is contemplated that members of this advisory committee shall be outstanding persons in the professions of medicine, surgery, dentistry, hospital administration and nursing.

Two bills propose a liberalization and clarification of the laws pertaining to hospital treatment, medical care, domiciliary care and related services for veterans, S. 1203, introduced by Senator Johnson, Colorado, and H. R. 3522, introduced by Representative Rankin, Mississippi.

A bill introduced by Representative Rogers, Florida, H. R. 3594, would authorize the Administrator of Veterans' Affairs to reimburse any accredited hospital for hospitalization and treatment, for a period not exceeding ten days, of a veteran where such hospitalization and treatment was of an emergency character.

H. R. 3629, introduced by Representative Maloney, Louisiana, proposes an appropriation of $2,500,000 to erect a general medical and surgical hospital and domiciliary facility in or near New Orleans for the care and treatment of women veterans.

The term "Veterans Administration facilities" would be redefined by a bill introduced by Representative Sikes, Florida, H. R. 3630, to include any private hospital or institution for which the Administrator of Veterans' Affairs may deem it necessary and proper to contract in order to provide hospital care for veterans suffering from injuries and diseases.

Miscellaneous

Representative Priest, Tennessee, has introduced H. R. 3561, proposing to amend the Public Health Service Act to authorize grants to the states for surveying their hospitals and public health centers and for planning construction of additional facilities, and authorize grants to assist in such construction. This bill is substantially the same as the Hill-Burton Hospital Construction Bill, S. 191.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

New Secretary of Medical Board.—Dr. Leonce J. Kosminsky, Texarkana, has recently been elected secretary of the state medical board of the Arkansas Medical Society, succeeding Dr. De Veaux L. Owens, Harrison.

CALIFORNIA

Student Awarded Gold Headed Cane.—Dr. Guerne W. de Lappe, San Francisco, was awarded the gold headed cane given each year to a member of the graduating class of the University of California Medical School, San Francisco. According to the University of California Clip Sheet, the award of the cane is an old English custom which was revived in 1939 by Dr. William J. Kerr, professor of medicine. Each year he presents a cane to the senior medical student who, in the opinion of his classmates and the faculty of the division of medicine, has demonstrated the most striking qualities of a true physician. Dr. David J. New, Piedmont, formerly of Monrovia, received first honorable mention and Dr. Jack Donald Thorburn, El Segundo, second honorable mention.

X-Ray Survey Center Planned.—A mass x-ray survey plan, calling for the establishment of a permanent x-ray survey center open to the public five days a week, has been unanimously approved by the board of directors of the Sacramento County Tuberculosis and Health Association. The plan will make it possible to offer free x-rays to every family in the city and county in the next two years. An estimated 500 families daily will be sent direct invitations by mail giving them specific appointments for x-ray examination, these to be sent after the mailing of literature explaining the purpose of the county wide program and a summary of the tuberculosis problem in the area. It is hoped to have the plan in full operation by fall, according to the *Bulletin* of the National Tuberculosis Association.

ILLINOIS

District Meeting.—Dr. Glen W. Doolen, Davenport, Iowa, was elected president of the Iowa-Illinois Central District Medical Association at its annual meeting on May 24, succeeding Dr. Paul P. Youngberg, Moline. Other officers include Drs. Joseph K. Hanson, Moline, vice president; James Dunn, Davenport, secretary, and Florens E. Bollaert, East Moline, treasurer. Among the speakers at the meeting were Dr. James L. Mudd, St. Louis, on "Empyema" and Dr. Herbert E. Schmitz, Chicago, "Management of Prolonged Labor." Dr. Andrew C. Ivy, Chicago, addressed the dinner session on "Some Contributions of Medicine to Survival on a Raft at Sea."

Chicago

Personal.—Horace L. Sipple, Ph.D., formerly associated with the American Can Company, has been appointed director of the research and educational program of the Evaporated Milk Association.

Special Society Election.—Dr. Frederick R. Schmidt was recently chosen president of the Chicago Dermatological Society. Other officers include Dr. Maurice J. Reuter, Milwaukee, vice president, and Dr. Marcus R. Caro, secretary-treasurer.

Pigeons to Be Tested for Pneumonia Virus.—Itinerant pigeons in Chicago will be tested in the city laboratories of the state department of health to determine if they are carriers of a virus type pneumonia, the Chicago *Sun* reported June 21. Similar tests made at the University of California on pigeons taken from the streets of Philadelphia resulted June 20 in an order by the Philadelphia Department of Health for extermination of the pigeons in the squares and parks, the *Sun* stated. The tests disclosed that 45 per cent of the birds carried a virus which is said to resemble psittacosis. Two tests will be made to identify the virus—one a test of the pigeon serum for the presence of antibodies, and the other to isolate the virus in the pigeon tissue. Recent pigeon tests made in Detroit revealed antibodies in the pigeon serum.

Cancer Committee Opens Information Bureau.—The Chicago Cancer Committee announces the opening of the cancer information bureau at 139 North Clark Street, where facts concerning cancer control and information about facilities for the diagnosis and treatment of cancer will be made available to the public. The bureau is being established in cooperation with the Field Army of the American Cancer Society. Dr. George E. Wakerlin is chairman of the Chicago Cancer Committee, which was organized in 1941 under the leadership of Dr. Ludvig Hektoen to coordinate the activities of all groups engaged in cancer control work in the Chicago area, to encourage research and education of the public and to assist in the establishment of diagnostic and treatment facilities. Dr. Hamilton R. Fishback is chairman of the committee of the information bureau.

INDIANA

Personal.—Dr. John A. Davis, Flat Rock, was chosen president of the Indiana Tuberculosis Association at its meeting in Indianapolis May 9, succeeding Dr. James F. Spigler, Terre Haute.

License Revoked.—The state board of medical registration and examination on March 27 revoked the license to practice medicine of Dr. Frank Morse Nichols, Warsaw and Winona Lake, because of a narcotic conviction.

New Diagnostic Treatment Building.—On June 10 a new diagnostic treatment building was opened at Clearview, Evansville, which expands the bed capacity from 16 to 32. The building cost $55,000. Speakers at the opening included Dr. Clarence C. Herzer, president of the Vanderburgh County Medical Society, and Congressman Charles M. LaFollette. Clearview is a private hospital for patients suffering from mental and nervous disease, alcoholism or drug addiction. Dr. Albert L. Crane is one of the owners and physician in charge.

Members of Hospital Regulation and Licensing Council.—Members of the newly created hospital regulation and licensing council of the Indiana State Board of Health, appointed recently by the governor, are:

Dr. Eldo H. M. Clauser, chairman, Muncie.
Mr. Albert G. Hahn, vice chairman, Protestant-Deaconess Hospital, Evansville.
Sister Amelia, R.N., St. Elizabeth Hospital, Lafayette.
Dr. David R. Johns, East Chicago.
Olive M. Murphy, R.N., Bartholomew County Hospital, Columbus.
Dr. Benjamin P. Linvill, Columbia City.
Mr. J. B. H. Martin, administrator, Indiana University Medical Center, Indianapolis.

Ex officio members are Mr. Otto F. Walls, director, state department of public welfare, Indianapolis, and Dr. Thurman B. Rice, secretary of the state board of health, Indianapolis, who after July 1 was to be succeeded by Dr. Leroy E. Burney, New Orleans, recently named state health commissioner. The council was set up by the 1945 legislature with authority to license, inspect and regulate hospitals.

MARYLAND

Twenty-Fifth Conference of State Board of Health.—The Maryland State Department of Health recently held its twenty-fifth annual conference in Baltimore. Sessions were held at the Johns Hopkins School of Hygiene and Public Health and at the state department of health. Among the speakers were:

Dr. Charles H. Halliday, Baltimore, Tuberculosis Control in Maryland.
Dr. Edwin L. Crosby Jr., Baltimore, Importance of Hospital Licensing.
Dr. G. Foard McGinnes, St. Louis, The Blood and Blood Derivaties Program of the American Red Cross.
Dr. Myron E. Wegman, New York, Indices of Nutrition.
A. W. Hedrich, Sc.D., Baltimore, Role of the Public Health Nurse in Promoting Birth Registration.

MASSACHUSETTS

University News.—Dr. Lewis H. Weed, Baltimore, chairman of the division of medical sciences of the National Research Council, gave the commencement address at Boston University School of Medicine, June 22, on "Some Aspects of Medicine in the Years Ahead."

Alonzo K. Paine Given Distinguished Service Key.—On June 16 Dr. Alonzo K. Paine was awarded a distinguished service key by the trustees of Tufts College in recognition of exceptionally loyal service to his alma mater, Tufts College Medical School. This recognition is made to a small group of individuals each year and is a joint award of the alumni association and the trustees of the college. As president of the Tufts Medical Alumni Association Dr. Paine has been responsible for organizing and completing the drive for funds for a new medical school building, to be erected at the New England Medical Center.

MICHIGAN

Changes in Health Officers.—Dr. Verne L. Van Duzen, Belding, has been appointed director of health for the Mecosta-Osceola health department, effective June 1. Dr. Ira O. Church, Coldwater, has resigned as director of the Branch County Health Department. Dr. James J. Croley, Houghton, has been appointed director of health of Kalamazoo County.

State Health Department Creates New Peninsula Office.—Dr. Wilbert J. M. Menke, a member of the teaching staff of the University of Michigan School of Public Health and of the school of medicine, has been appointed director by the state health commissioner of the upper peninsula office of the Michigan Department of Health. The new office was created by the 1945 legislature and will have offices at the Pinecrest Sanatorium, Powers. *Michigan Public Health* reports that the new office was established to make possible a more effective public health program in the upper peninsula. The thirteen county health departments in the upper peninsula have operated in the past without the immediate assistance and supervision of the state health department. They have been isolated from the central office in Lansing by distance and from one another by a lack of coordinating supervision. Two counties do not have health departments.

MINNESOTA

State Medical Election.—Dr. Edwin J. Simons, Swanville, was elected president of the Minnesota State Medical Association at the meeting of the house of delegates in St. Paul May 19-20. He will succeed Dr. Edward L. Tuohy, Duluth, on Jan. 1, 1946. Other officers chosen include Drs. Max Alberts, St. Paul (deceased) and Winslow C. Chambers, Blue Earth, vice presidents; Benjamin B. Souster, St. Paul, secretary and William H. Condit, Minneapolis, treasurer. The house of delegates formed a nonprofit corporation which will be independent of the state medical association but whose board of directors will be made up of two physicians from each of the nine councilor districts and three at large. The first meeting was to be held June 17, according to the state medical journal. The journal also announced that the committee on sickness insurance of the state association has changed its name to the committee on medical care. At the time of this report it was not yet decided whether the medical service plan to be promulgated by the corporation was to be coordinated with the Blue Cross.

MISSOURI

Pilgrimage to Beaumont's Grave.—The Lloyd R. Boutwell Post, No. 136, American Legion, held memorial services at the grave of Dr. William Beaumont at the Bellefontaine Cemetery, St. Louis, May 30. This is an annual service of the Boutwell Post.

Personal.—Dr. Edward W. Cline, Platte City, health officer of Platte County, has been appointed to a similar position in charge of the newly merged city-county health department of Jasper County with offices in Joplin.——Dr. George A. Mellies was guest of honor at a dinner May 31 given by the staff of the Christian Hospital, St. Louis, in recognition of his completion of fifty years in the practice of medicine. He was presented with a wrist watch.

MONTANA

Board Election.—Dr. Cedric H. Nelson, Billings, was elected president of the state board of medical examiners April 2 in Helena, Dr. Edmund A. Welden, Lewistown, was chosen vice president and Dr. Otto G. Klein, Helena, was reelected secretary. Dr. Patrick E. Kane, Butte, was reappointed a member of the board for a seven year term.

Health League Takes Permanent Offices.—The Public Health League of Montana has established permanent offices in the Power Block, Helena. All communications should be addressed to Post Office Drawer 1142, Helena. The league will serve as a clearing house for public relations activities of various affiliated groups, aid in conducting programs of information regarding affairs and activities which affect public health, cooperate with existing public health agencies and protect the interests of the public through health campaigns, crusades and other activities. Mrs. H. W. Peterson, Billings, field commander, northwest region, Field Army, American Cancer Society, is president of the organization; Rev. Frank L. Harrington, Butte, representing the Catholic Hospital Association, is vice president; Milo F. Dean, Great Falls, representing the Montana Hospital Association, is secretary-treasurer. D. W. Bowler, Helena, has been selected league manager and Margaret Applegate, Helena, office secretary. In addition to Father Harrington, Mr. Dean and Mrs. Peterson, the directors of the league include Dr. James M. Flinn, Helena, Montana Medical Association; Mrs. Frances MacDonald, Great Falls, Montana State Nurses Association; E. A. Kuntz, Helena, Montana Optometric Association; Joe L. Markham, Butte, director at large; George Gosman, Dillon, pharmaceutical association; Harvey Fearn, Bozeman, Montana State Dental Association, and George Hutton, Billings, tuberculosis association.

NEW YORK

Ninety-Four Years of Age.—Dr. Frederick N. Winans, Franklin, celebrated his ninety-fourth birthday May 28. He practiced in Gilbertsville for twenty years and has been in Franklin fifty-one years.

Progress of Plan for Distribution of Blood Plasma.—Provisional plans for the organization of a statewide program to distribute blood plasma and blood derivatives in New York State have been drawn up by the state department of health, through its office of medical administration and division of laboratories and research, in collaboration with the New York State Association of Public Health Laboratories, the state hospital association and the Medical Society of the State of New York. The general distribution will be made through approved public health laboratories for the purpose of establishing a supply for the smaller urban and rural communities. While no charge will be made for the plasma, it is expected that individuals benefiting from its use will be made responsible for obtaining donors who will give blood for its replacement. According to *Health News,* other features of the projected service are the establishment of a center of information as to where blood of unusual types may be obtained on short notice and encouragement of the use of standardized equipment in all cooperating laboratories, making possible an interchange of facilities in emergencies. Of particular importance is the anticipated promotion of a continued graduate medical program, in cooperation with the state and county medical societies, which will provide information concerning the value and use of whole blood and its derivatives. The proposed program is being developed as a result of the passage of enabling legislation and an appropriation by the legislature of $100,000.

New York City

License Reinstated.—The license to practice medicine of Dr. Herman L. Kasha, revoked in 1941, was reinstated as of July 1.

Personal.—Philip S. Platt, Ph.D., executive director of the New York Association for the Blind, was chosen president of the Greater New York Council of Agencies for the Blind at its annual meeting, June 5. Berthold Lowenfeld, director of educational research, American Foundation for the Blind, was elected secretary-treasurer.

Dr. Freitag Surrenders.—Dr. Abraham Freitag, Brooklyn, who pleaded guilty recently to charges of diverting to the black market bandage material for which he had a priority, surrendered June 18 to U. S. Marshal James E. Mulcahy to begin a prison term of three years. He was also fined $100,000, which had not been paid at the time of this report (THE JOURNAL, June 16, p. 532).

Physician Receives Anniversary Volume.—Dr. Eli Moschowitz, consulting physician of the Mount Sinai Hospital, was presented June 27 with a special edition of the *Journal of the Mount Sinai Hospital* in commemoration of his recent sixty-fifth birthday. Dr. Moschowitz graduated at Columbia University College of Physicians and Surgeons in 1900 and served his internship at Mount Sinai. In 1920 he joined the staff of the medical service; in 1941 he was named attending physician and in 1944 consultant.

NORTH CAROLINA

Honor Physicians Over Seventy.—Nine Mecklenburg County physicians, seven of them more than 70 years old and the others to be 70 in September, were honored by the Mecklenburg County Medical Society at a dinner dance in Charlotte June 1. The physicians who are already 70 or more are Drs. Robert L. Gibbon, Albert M. Whisnant, Calvin S. McLaughlin, James G. Johnston, Thomas M. McCoy and James R. Alexander, all of Charlotte, and Thomas N. Reid, Matthews. The other two are Drs. Lorenzo D. McPhail and William M. Strong, both of Charlotte.

Southern Pediatric Seminar.—The twenty-fifth session of the Southern Pediatric Seminar will be held at Saluda, July 16-28. Among the speakers will be:

Dr. Samuel F. Ravenel, Greensboro.
Dr. Frank H. Richardson, Black Mountain.
Dr. Owen H. Wilson, Nashville, Tenn.
Dr. William L. Funkhouser, Atlanta.
Dr. Charles J. Bloom, New Orleans.
Dr. John LaBruce Ward, Asheville.
Dr. Francis B. Johnson, Charleston, S. C.
Dr. William Weston, Columbia, S. C.
Dr. Daniel Lesesne Smith, Saluda.
Dr. W. Ambrose McGee, Richmond, Va.
Dr. Angus M. McBryde, Durham.
Dr. Alfred A. Walker, Birmingham, Ala
Dr. Richard M. Pollitzer, Greenville, S. C.
Dr. Stewart H. Welch, Birmingham.
Dr. Wilburt C. Davison, Durham.
Dr. Oren Moore, Charlotte.
Dr. Oscar L. Miller, Charlotte.
Dr. Antonio J. Waring, Savannah, Ga.
Dr. Kenneth M. Lynch, Charleston.
Charles B. Bray, D.D.S., Birmingham
Dr. Joseph Warren White, Greenville, S. C.
Dr. Hamilton W. McKay, Charlotte.
Dr. Robert W. McKay, Charlotte.
Dr. Philip A. Mulherin, Augusta, Ga.
Dr. Luther W. Holloway, Jacksonville, Fla
Dr. Warren W. Quillian, Miami, Fla.
Dr. Madison Hines Roberts, Atlanta.
Dr. Mylnor W. Beach, Charleston, S. C.
Dr. Daniel Lesesne Smith Jr., Spartanburg, S. C.
Dr. Julian P. Price, Florence, S. C.
Dr. Frank Lee Bivings, Atlanta.
Dr. Jay M. Arena, Durham.
Dr. Robert B. Lawson, Winston-Salem.
Dr. Hughes Kennedy Jr., Birmingham.
Dr. Amos Christie, Nashville.

The participants will present papers, conduct clinics and hold various round table discussions. Dr. Daniel Lesesne Smith, Saluda, is registrar for the seminar.

OKLAHOMA

Paul Fesler Returns to University.—Mr. Paul H. Fesler has resigned as executive secretary of the Oklahoma State Medical Association to return to the University of Oklahoma School of Medicine, Oklahoma City, as administrator of hospitals. Mr. Fesler will continue with the state medical association on a part time basis pending the appointment of a successor.

Physician's Library Given to County Medical Society.—The medical library of the late Dr. John Frederick Bolton, consisting of about 100 volumes, has been transferred to the library of the Tulsa County Medical Society through the courtesy of St. John's Hospital, Tulsa. It will be placed in the special section to be indicated by a bronze plaque, presented to the medical library by Dr. Bolton's family. The *Bulletin* of the Tulsa County Medical Society announces that members of the Bolton family plan to keep the library active through the years by the addition of new textbooks.

PENNSYLVANIA

Personal.—Dr. Edward M. Iland, Coraopolis, has been appointed district medical director for Allegheny County, in the absence of Dr. Angelo M. Williams, Pittsburgh, who is in military service.——Dr. John Webb Vaughn, Bergery, was guest of honor at a dinner, May 10, in recognition of his completion of fifty years in the practice of medicine.

Survey of the Blind.—Miss Annette Dinsmore, field supervisor of the home instructors for the adult blind, Pennsylvania Council for the Blind in the state department of welfare, is securing some data in regard to deaf-blind persons in Pennsylvania. Her work is a part of the program of the American Foundation for the Blind to secure as much data as possible on a representative sampling of deaf-blind persons in order to assist in determining their greatest needs. P. C. Potts, assistant director, American Foundation for the Blind, New York, is planning to devote considerable time to the problem.

Philadelphia

Dr. Ingleby Resigns as Professor of Pathology.—Dr. Helen Ingleby, since 1924 professor of pathology at Woman's Medical College of Pennsylvania, resigned June 15 to head on a full time basis the division of pathology in the laboratories of the Jewish Hospital.

New Professorship in Ophthalmology.—On June 16 the University of Pennsylvania received a gift of $155,000 from the estate of the late Dr. George E. de Schweinitz, who died Aug. 22, 1938. According to the New York *Times*, the bequest will be used to establish a fund to support the department of ophthalmology and to create a professorship to be known as the "William F. Norris and George E. de Schweinitz Professorship of Ophthalmology." Dr. Norris was the first professor of ophthalmology at the medical school and Dr. de Schweinitz was professor from 1902 until 1929, when he became emeritus professor.

Special Society Election.—Dr. Gerald H. J. Pearson was chosen president of the Philadelphia Psychoanalytic Society at its annual meeting June 9. Other officers include Drs. George W. Smeltz, Pittsburgh, vice president, and LeRoy M. A. Maeder secretary-treasurer.

The Jarecki Lecture.—Dr. Harry C. Solomon, professor of psychiatry at Harvard Medical School, Boston, and head of the department at the Boston Psychopathic Hospital, delivered the eleventh annual Jarecki Memorial Lecture at the Jewish Hospital, May 2, on "The Effects of War on Psychiatry."

Pittsburgh

Medical Bulletin Dedicated to Women Members.—The *Pittsburgh Medical Bulletin* for June 2 was dedicated to the 58 women members of the Allegheny County Medical Society. Dr. Zoe Allison Johnston, elected in 1944, was the first woman to be chosen president of the society.

TENNESSEE

Personal.—William Henry Hollinshead, Ph.D., associate professor of anatomy at the Duke University School of Medicine, Durham, N. C., will be visiting associate of anatomy at the University of Tennessee College of Medicine, Memphis, during the summer quarter, according to *Science*.——Dr. Julian E. Williams, Blountville, recently resigned as health officer of Sullivan County.——Dr. John W. Shackelford has been appointed assistant health officer of the Memphis and Shelby County Health Department, succeeding Dr. W. D. Burkhalter (THE JOURNAL, May 12, p. 146).

UTAH

Personal.—Dr. Thomas J. Howells on May 18 was named director of the Salt Lake County Health Department. Dr. Howells has served as superintendent of the Salt Lake County General Hospital and also as health commissioner of Salt Lake City.——Dr. Edward L. Van Aelstyn, Price, has resigned as health officer of district number 3, including Carbon, Emery, Grand and San Juan counties, effective June 1, to enter private practice.

WASHINGTON

Physicians Sue Medical Society.—Drs. John M. Howell and Roy H. Blender, Renton, are said to have filed a suit in Superior Court against the King County Medical Society "to force the society to permit them to practice in the new Renton Hospital" according to the Seattle *Times*, May 25. The use of the hospital was said to be denied the physicians because they were not members of the society, it was stated. The King County Medical Service Corporation was also named a defendant in the suit. The plaintiffs accused the society of conspiring with the medical service corporation to acquire a "monopoly" for members of the society in practicing medicine in the county. It was said that the corporation and the society also were charged with conspiring to "eliminate competition" in furnishing medical and hospital services to the public on the prepayment or monthly payment plan. Others named as defendants include the Valley Hospital Foundation, which operates Renton Hospital; Dr. Harold E. Nichols, Seattle, president, and other officers and trustees of the society; Dr. Erroll W. Rawson, Seattle, who was identified as president of the medical service corporation but who no longer holds that office; Dr. Karl H. Van Norman, superintendent of Doctors Hospital, Seattle, and officers and trustees of the Valley Hospital Foundation. Dr. Howell and Dr. Blender are affiliated with the Medical Security Clinic, which has offices in Seattle, Renton, Kirkland, Winslow and Ravensdale.

WEST VIRGINIA

Tumor Clinic Formed.—A tumor clinic has been organized in Fairmont under the joint sponsorship of the Marion County Medical Society and the county health department. Nursing service and follow-up work is being provided by the personnel of the health department. The clinic will be held on the first and third Thursdays of each month.

Changes in Health Officers.—Dr. Elias W. Langs, U. S. Public Health Service Reserve, acting director of the division of communicable diseases, state health department (THE JOURNAL, January 27, p. 238), has been appointed health officer of Kanawha County, succeeding Dr. Albert M. Price, who

resigned some months ago and is now engaged in private practice in Charleston. Dr. Thomas E. Romine, Charleston, who has been acting county health officer, has been named assistant to Dr. Langs.

HAWAII

Territorial Election.—Dr. Eric A. Fennel, Honolulu, was reelected president of the Hawaii Territorial Medical Association at its annual meeting in May. Other officers include Drs. Louis A. R. Gaspar Jr., secretary, and Lyle G. Phillips, treasurer, both of Honolulu. Dr. Arthur Gordon Hodgins, Honolulu, was named president emeritus of the association.

Society News.—A recent meeting of the Honolulu County Medical Society was addressed by the following:

Dr. Martin H. Lichter, Critical Analysis of Medical Economic Problems in Hawaii.
Dr. Harold M. Patterson, Aims and Aspirations of the Territorial Association of Plantation Physicians.
Lieut. Col. Herman L. Meltzer, M. C., Some of the Medical Lessons Learned in World War II—Army.
Comdr. Albert W. Hobby (MC), Some of the Medical Lessons Learned in World War II—Navy.
Capt. Howard K. Gray (MC), Some of the Surgical Lessons Learned in World War II—Navy.
Col. Forrester Raine, M. C., Some of the Surgical Lessons Learned in World War II—Army.

Health Committee to Broaden Activities.—The chamber of commerce of Honolulu in May approved a plan for streamlining and broadening the scope of activities of its public health committee. According to the Honolulu *Advertiser*, Dr. Forrest J. Pinkerton, Honolulu, chairman of the committee, announced that as a result of the adoption of his reorganization plan the former Oahu health council, representing all social service and related health groups, would be reactivated, permitting virtually all public health activities to be coordinated through the relationship between the public health committee and other welfare and public health agencies. According to the new plan, certain ex officio members of the public health committee by virtue of their positions with other public health agencies will be discontinued and will have their representation through the Oahu health council. An advisory committee is to be organized from among the membership of the public health committee. Raymond G. Nebelung, new executive director of the health committee, is to be charged with coordination of the various groups, working under Dr. Pinkerton's direction, and a health specialist, Mrs. Allice Spillane, formerly with the Washington state health department, will be added to the staff.

GENERAL

Sir Alexander Fleming Tours United States.—Sir Alexander Fleming, London, discoverer of penicillin, is touring the United States as a representative of the British Ministry of Supply.

Pediatric Examinations to Be Held in Atlantic City.—The American Board of Pediatrics announces that the oral examination will be held in Atlantic City at the Hotel Claridge, December 7-9. This change was made because hotel reservations in New York were unavailable. The written examination of the board will be locally under a monitor, October 19.

Meetings Canceled.—The American Congress of Physical Medicine announced that its annual scientific and clinical session, scheduled to be held in New York, September 5-8, has been canceled. Marion G. Smith, B.Sc., 30 North Michigan Avenue, Chicago 2, is the executive secretary.——The annual convention of the American Academy of Ophthalmology and Otolaryngology which was scheduled for October has been canceled.

Medical Illustrators to Organize.—Twenty-five medical illustrators will meet at the University of Illinois College of Medicine, July 16-19, to create an association of medical illustrators. The session is the result of a two year study and speakers will include Dr. Morris Fishbein, Editor of THE JOURNAL; Dr. Eben J. Carey, Milwaukee; Dr. Malcolm T. MacEachern, Chicago; Thomas G. Hull, Ph.D., director scientific exhibit, American Medical Association, and Carl G. Hartman, Ph.D., Urbana, Ill. One session will be held at the Museum of Science and Industry, Jackson Park, Chicago.

Mental Hygiene Committee Comments on Psychiatric Facilities for Discharged Veterans.—On June 22 the National Committee for Mental Hygiene issued a statement through the United Press that figures recently made available "reveal a staggering need for the creation of psychiatric facilities for the care of mentally disabled veterans." This need was emphasized as a result of the estimate that 500,000 veterans had been discharged from the services for psychiatric reasons by the end of 1944. Facilities are also needed to aid the 1,500,000 men rejected for service because of psychiatric reasons, it was stated. A survey showed twenty-five states without a community clinic for psychiatric care and "vast areas in other states where no psychiatric help is available." Of the total number of established hospitals and clinics throughout the country, only 139 certified their preparedness to treat mental casualties. "With the best will in the world the Veterans Administration and the state vocational rehabilitation bureaus cannot provide psychiatric treatment when neither clinics nor psychiatrists are available," the announcement said. It further reported that the estimated cost to the taxpayer was $30,000 for every hospitalized psychiatric casualty of World War I.

Government Services

Estella Warner Goes to Kansas City

Dr. Estella Ford Warner, senior surgeon, U. S. Public Health Service, district three, with headquarters in Chicago, has been transferred to district seven, with headquarters at Kansas City, Mo., and with the title medical director. The change is effective July 1.

Grants in Aid for Cancer

Nine grants in aid totaling $79,377 were approved at the twenty-eighth meeting of the National Advisory Cancer Council recently at the National Cancer Institute of the U. S. Public Health Service, Bethesda, Md. The total is the greatest amount ever granted at one time by the council and will be expended as follows:

Harvard University, Boston, $24,500 for the study of the relation of steroid hormones to growth and tumors under direction of Dr. James H. Means. Drs. Fuller Albright and Joseph C. Aub will also participate.
Mount Sinai Hospital, New York, $10,775 for clinical studies on gastric cancer under the direction of Franklin Hollander, Ph.D.
Harvard University, an additional $10,000 for the study of the pathology of cancer of the stomach, peptic ulcer and gastritis, with Dr. Shields Warren in charge.
University of Cincinnati, Cincinnati, $10,000 for clinical studies of gastric cancer to be conducted by Dr. Leon Schiff.
Northwestern University, Chicago, $8,500 for research in cancer education. Dr. Andrew C. Ivy will supervise the work.
Haskins Laboratories, New York, $5,000 research on the virus-like agent in mammary cancer of mice. Paul A. Zahl, Ph.D., will direct.
Detroit Institute of Cancer Research, Detroit, $6,152 for study in relation of certain types of diets to induced cancer in rats with Wilhelmina F. Dunning, Ph.D., in charge.
New York University, New York, $3,000 in a study of Hodgkins disease by Robert Chambers, Ph.D.
University of Minnesota, Minneapolis, $1,450 studies on leukemia in mice, conducted by Dr. Arthur Kirschbaum.

Urge Expansion of Services for Children

A recommendation has been presented to President Truman for immediate expansion of health, welfare, education and other federal-state services for children with an additional $75,000,000 appropriation for the fiscal year 1946. The recommendation was made at the conclusion of a year's study by the National Commission on Children in Wartime, according to the New York *Times*. A $50,000,000 addition to the current $6,000,000 grants-in-aid appropriation to the states for maternal and child health services was recommended, this sum to be broken down into a $10,000,000 dental care program for young children, a $15,000,000 school health program and a $25,000,000 program for the care of mothers, infants and preschool children. A $25,000,000 increase over the less than $4,000,000 in current yearly grants for crippled children's services was asked, $15,000,000 of which would go to the victims of rheumatic fever and heart disease, which kill and cripple more grade school children than any other cause except accidents; the rest to be divided equally between orthopedic and other types of crippling such as diabetes, allergies and epilepsy. The *Times* states that the period of ten years was set as the logical limit on providing through federal and state funds such all inclusive service. It was recommended that after the fiscal year 1946 no maximum be specified for either maternal and child health or crippled children's services. Within the same ten years, the commission contended, this nation should provide child welfare services reaching into every county of every state and should have greatly expanded the community resources for care of children of employed mothers, for foster care for dependent children, for detention care of children who come before juvenile courts and for return of child waifs and runaways to their own communities.

Foreign Letters

LONDON

(From Our Regular Correspondent)

June 2, 1945.

The Problem of Medical Demobilization

The termination of the war in Europe does not promise much relief in the near future of the shortage of doctors in civil practice. In a letter to the *Times* Lord Moran, president of the Royal College of Physicians, says that they have fallen below the margin of safety. There is 1 general practitioner for 2,640 people in this country, while there is 1 for 350 men in the army. On the invitation of the director general of the Army Medical Service Lord Moran was able, with the registrar of the college and Prof. L. S. P. Davidson, to go to Belgium, the Netherlands and Germany to talk over problems of demobilization with medical officers in the army. They were able to hold ten meetings and to have many informal discussions with more than 1,000 medical officers. Many of these men had not seen their families for five years. They had been disturbed by the report that the release of doctors would not keep pace with general demobilization. The trouble is that the army medical authorities are still uncertain of their commitments in the war with Japan. They reckon that for every doctor required for a given force in Europe 3 doctors will be required in the Far East on account of the long lines of communication, wastage from tropical diseases and the lack of civil hospitals at the base, such as are provided in England. Meanwhile the army in Europe is saddled with responsibility not only for the soldiers but for the civilians of many nations. Only a third of the beds in military hospitals in Italy are occupied by British soldiers. Of 211,813 soldiers admitted to military hospitals in the Middle East in 1944 only 87,157 were British. Nevertheless, the army medical authorities have determined to solve this problem of demobilization and have set about ruthlessly cutting down establishments except in the Far East. They believe that they can release most of the general duty officers without replacement by men from general practice.

The position of specialists is less happy. In the first eleven demobilization groups there are 1,431 doctors, of whom 467 are specialists. The army contends that some of the latter can be released only if they are replaced by specialists not now in the army. However, it is hoped that the vast majority of both general practitioners and specialists in the first eleven groups will be demobilized by autumn.

The Central Medical War Committee (a medical body which controls medical recruiting) announces that doctors will be released from the armed forces in groups, determined by age and length of service. These releases will be possible partly owing to reduction in strength of the forces but partly also as a result of continued recruitment. One of the objects of the latter is to increase the releases. Arrangements will be made to transfer to civilian employment, out of their turn and with their consent, a limited number of doctors who are urgently required for work of national importance. They will be liable to recall to the forces if they leave the work for which they are transferred. It seems that at present little can be done to relieve the shortage of doctors in civilian practice. Indeed, every man and woman who can be spared is being sent to the forces. The main source of supply is a pool of young practitioners who have completed posts at hospitals. These are rarely allowed to accept even short term engagements in general practice, although urgent appeals for their services as assistants are made. Also they are not granted deferment to enable them to take examinations for higher degrees. Many civilian doctors are carrying intolerable burdens.

Arrangements have been made for the postgraduate training of doctors leaving the services. Those who joined within a year or so of qualifying are offered paid posts in hospitals. Those who were established in general practice before joining are offered a refresher course free of cost with traveling expenses paid and a subsistence allowance. For medical officers who were training for a specialist career before joining or are regarded as suitable for such training, paid posts of the "registrar" type in teaching and other hospitals will be provided.

Hospital Services in London and the Surrounding Area Inadequate

In 1941 the minister of health commissioned two physicians, Dr. A. H. M. Gray and Dr. Andrew Topping, to report on hospital services in London and the surrounding area and to make recommendations. Their report, which has just been published, shows that no adequate and comprehensive hospital service is attainable without considerable give and take on the part of both the local authorities and the voluntary hospitals. The most urgent and the most important single improvement would be in the medical staffing of hospitals. To make the best use of the specialists available, decentralization from London is urged with their appointment at the principal hospitals, termed "district hospitals," in the surrounding area. Payment for their services should be on a scale which will adequately repay them for breaking their ties in London. In quantity or in quality, or in both, accommodation is found deficient in every area. A large building program is needed to raise the standard to an adequate level.

The Promotion of Sociability at the Royal College of Surgeons

The council of Royal College of Surgeons has decided to institute monthly subscription dinners in the college for fellows and members of the college and members of the specialist associations linked with it. These will be held on the evening of the Wednesday preceding the second Thursday of the month. Applications must be made to the secretary at least a week before the date of the dinner accompanied by a payment of $4, the inclusive charge for each dinner. The council's object is to give those associated with the college opportunities of meeting socially more often. If it is found that the opportunity for dining in the college is properly appreciated, arrangements will be made to hold these dinners at shorter intervals. In the plans for the restoration and development of the college after the war damage it is intended that facilities for lunching and dining shall be greatly increased.

Low Mortality of American Wounded Treated in Britain

The medical department at the headquarters of the base in Britain of the United States Army has just stated that nearly 500,000 wounded American soldiers, the equivalent of some thirty divisions, have been evacuated from the continent of Europe since D day to United States medical installations in Britain. On February 8 casualties numbering 129,500 were in hospitals in Britain, which represented the peak number under care at any one time. There were ninety-nine hospitals and five big convalescent camps. The mortality among the patients was 0.26 per cent of total admissions. Approximately 61 per cent of all patients were returned to duty.

Belgian Visitors

A third group of Belgian professors is now visiting universities and research institutions in this country at the invitation of the British council. They include A. E. Michotte van den Berck, professor of experimental pathology at Louvain, A. E. Gratia, professor of parasitology and bacteriology at Liége, and J. A. H. Rodhain, director of the Institute of Tropical Medicine in Antwerp. The visit will last a fortnight.

BRAZIL

(From Our Regular Correspondent)

RIO DE JANEIRO, May 18, 1945.

Pharmacologic Study of a Curare-like Alkaloid

The therapeutic importance of curare is somewhat hindered by the disadvantages of its being difficult to obtain and of presenting a great variability of its pharmacologic properties; hence the reason why several investigators have in recent years proposed the use of some alkaloids with curare-like properties but easier to obtain and pharmacologically more constant, such as erythroidin hydrochloride, extracted from the seeds of Erythrina americana by Burman in 1940, or the synthesized alkaloid quinine methylhydrochloride, prepared by Harvey in 1940 and used by Bennett in 1941 in several clinical cases. Drs. Oswaldo V. Brazil, Roched A. Seba and J. S. Campos of the Instituto Vital Brazil of Niteroi, state of Rio de Janeiro, have published the first report of a series of systematic investigations on plants of the Amazon valley that could be used instead of curare. The report presents the results of the pharmacologic study of Chondrodendron platyphyllum, a plant of the Menispermaceae family abundantly found in that region of Brazil.

The watery extract of the plant and the alkali insoluble alkaloid from it possess the paralyzing activity, though of less potency than that of curare. The action also differs because this drug does not cause a previous stage of excitation in dogs, is more active when introduced intravenously and produces sudden muscular shocks in the posterior limbs of mice during the preagonic stage. The methylation of this alkali insoluble alkaloid increases its activity more than ten times on mice, rats and pigeons, making the methylated fraction more powerful than the majority of the samples of curare. Experiments performed on rats have proved that the action of the Chondrodendron methylated alkaloid is typically peripheral. The antagonistic action of neostigmine, which could prevent the death of the animals that had received two minimum lethal doses of either curare or the methylated alkaloid, suggested that the drug does not cause intense collateral toxic action on the circulatory system. The comparison between the minimum lethal dose for the mouse, the rat and the pigeon, of the curare sample used, of the watery extract of Chondrodendron, of its alkali insoluble alkaloid and of a methylated fraction of the latter showed a great difference of sensibility of the several kinds of animals to the various curarizing substances.

Intestinal Tuberculosis

Dr. José Feldman of the department of pathology of the University of Belo Horizonte, state of Minas Gerais, has recently published a paper in which he reports the results of the last 443 necropsies performed at that department with the aim of ascertaining the frequency of intestinal tuberculosis. Of the total of 443 necropsies, tuberculosis of all forms was present in 88 cases, or 19.8 per cent, with the following distribution of localization: respiratory system alone 28, respiratory and digestive systems 45, respiratory and other systems except the digestive 5, digestive system alone 6, and organs or systems other than respiratory and digestive 4. In 29 cases the disease was present under the form of generalized miliary tuberculosis, of which the respiratory and digestive systems were involved in 29 cases (100 per cent), the spleen in 21 cases, both kidneys in 10, the pericardium in 5, the meninges in 4, the tonsils in 3, the larynx in 1, the trachea in 2, the cerebrum in 1, the urethra and urinary bladder in 1 and the feminine genitalia in 5. In 12 of the cases of miliary tuberculosis the liver showed specific lesions without involvement of the gastrointestinal tract. The distribution of the tuberculous lesions in the different parts of the digestive system was esophagus 1, stomach 1, jejunum 2, ileum 15, cecum 11, colon 3, liver 25, peritoneum 18 and mesenteric lymph nodes 17.

Pulmonary Lavage for Diagnosis of Active Tuberculosis

Dr. Manoel De Abreu, a pioneer worker in the development of the miniature x-ray film for the mass detection of pulmonary tuberculosis, and also a distinguished practitioner of radiology at Rio de Janeiro, has just published a detailed description of his new method of pulmonary lavage for the diagnosis of pulmonary tuberculosis. Pulmonary (or bronchopulmonary) lavage consists essentially in the introduction of 40 cc. of isotonic solution of sodium chloride into the trachea through the intercricothyroid space ten minutes after a very slow injection of 10 cc. of a 0.5 per cent solution of a local anesthetic. After the introduction of the solution the patient's posture is slowly changed from upright to lateral, first to the right then to the left, and to a slight Trendelenburg position, to allow the various parts of the lungs to be in contact with the solution. The liquid is at last expelled through coughing and expectoration, the patient being in the genupectoral position. By this method the carriers and noncarriers of germs are definitely identified, and even the germ laden material discharged by each of the lungs can be ascertained. The technic causes little discomfort to the patient and is so simple and rapid that as many as ten or twenty examinations can be performed within a two hour period, if the proper equipment is at hand. The method is still in the experimental stage.

Brief Items

Drs. Luis Valverde Chinel and Vito Arce Reyeros, from Bolivia, arrived at Rio de Janeiro last month to follow a postgraduate course in bacteriology, parasitology and immunology at the Oswaldo Cruz Institute of Rio de Janeiro under fellowships awarded by the Division of Intellectual Cooperation of the Ministry of Foreign Affairs of Brazil. Dr. Reyeros is secretary general of the Bolivio-Brazilian Cultural Institute for the scientific interchange between the two countries.

Dr. J. C. Brassantini of Montevideo, Uruguay, now at Rio de Janeiro, was present at the last meeting of the National Academy of Medicine, where he read a paper on the roentgenologic diagnosis of pneumonia in the adult.

Marriages

ALBERT BENSEN VAN VRANKEN, Schenectady, N. Y., to Mrs. Mary Merriam Ross of Skaneateles in Syracuse, April 14.

STEWART INGLIS ADAM, West Collingswood, N. J., to Miss Phyllis Berrian Adams of Bedford Hills, N. Y., June 2.

JACK M. SIMMONS Jr., Denver, to Lieut. Anna Belle Longwater of Savannah, Ga., in Longview, Texas, recently.

HERBERT PECKOVER HARGETT, Maysville, Ky., to Miss Marion Hurlbut of Pelham Manor, N. Y., June 9.

NORBERT MENUHIN, Newark, N. Y., to Miss Marianne Grainer of Phelps in Rochester, May 27.

DAVID D. DEXTER, Richmond, Va., to Miss Edna Jane Nesbitt of Verona, N. J., and Richmond, June 9.

PAUL A. RIEMENSCHNEIDER, Cleveland, to Miss Mildred McCarthy of Manlius, N. Y., May 12.

JAMES R. ALLEN, Oakland, Calif., to Miss Lois Christine Armagost in Rochester, N. Y., June 2.

HARVEY CHADWICK PAULEY Jr., Belmont, Mass., to Miss Mildred Fraser of St. Louis, May 5.

ALDONA A. JUSKA, Oak Park, Ill., to Max R. Kennedy, D.D.S., in Nome, Alaska, April 19.

RONALD CLARE BISHOP, Almont, Mich., to Dr. Nancy Ventress Rider of Brooklyn, April 22.

PRESTON S. HOUK, Portland, Ind., to Miss Wilma Jean Curley in Detroit, April 7.

JAMES MATTHEW SAN to Miss Mary Alice Fisher, both of Durham, N. C., May 10.

KENNETH J. KELLEY, Grove City, Minn., to Miss Viola Carter of Ada, April 2.

Deaths

Luther Halsey Reichelderfer ⊕ Washington, D. C.; Columbian University Medical Department, Washington, D. C., 1899; formerly clinical professor of surgery at his alma mater, now known as the George Washington University School of Medicine; served as a member of the faculty of the Business High School, where he remained for four years as an instructor of mathematics; served as an intern at Garfield Hospital from 1899 to 1900 and was superintendent and chief resident physician from 1900 to 1907; medical director of the George Washington University Hospital, 1907-1908; member of the surgical staffs at Garfield, Children's and Tuberculosis hospitals until retirement from active practice in 1924; member of the consulting staffs of the Children's and Garfield hospitals; past president of the District of Columbia Commission on Licensure and the Medical Society of the District of Columbia; served as president of the board of commissioners of the District of Columbia; member of the Hippocrates-Galen Medical Society, Clinico-Pathological Society and the Association of Military Surgeons of the United States; one of the founders and life member of the American College of Surgeons; for many years an officer in the District of Columbia National Guard, serving as a first lieutenant and inspector of rifle practice, advancing to the rank of lieutenant colonel of infantry and chief surgeon; participated in a number of national rifle matches; during World War I was a lieutenant colonel in the medical corps of the U. S. Army in France; colonel, medical reserve corps, U. S. Army, not on active duty; since 1932 a member of the board of trustees of George Washington University, receiving the honorary doctor of laws from the university in the same year; died June 19, aged 71, of coronary occlusion.

Robert Hamilton Pierson ⊕ Colonel, U. S. Army, retired, Cazenovia, N. Y.; Syracuse University College of Medicine, 1898; Army Medical School, 1903, School of the Line, 1920, Army War College in 1922; entered the U. S. Army in 1902; promoted through the various grades to that of colonel on Feb. 18, 1929; retired for disability in line of duty on Jan. 31, 1933; served at military posts throughout the United States, Cuba, Alaska, the Philippines and the Panama Canal Zone; during World War I was chief surgeon on the Fifth Division staff, later becoming chief surgeon of the Sixth and Seventh Army; after the armistice, remained in Germany with the Army of Occupation; on his return to the United States, assigned to the Philippine Islands and spent considerable time in China, Japan and India on special government assignments; later appointed chief surgeon at Fort Sill, Okla., after which he was transferred to New York to become inspector instructor in charge of medical teaching in the New York National Guard; held the Distinguished Service Medal and the Silver Star; died in the Memorial Hospital, Syracuse, June 2, aged 70, of cerebral hemorrhage and diabetes mellitus.

James Evans Stowers ⊕ Kansas City, Mo.; Johns Hopkins University School of Medicine, Baltimore, 1913; specialist certified by the American Board of Surgery; member of the Western Surgical Association and the Kansas City Academy of Medicine; fellow of the American College of Surgeons; past president of the Kansas City Southwest Clinical Society and the Kansas City Surgical Society; chairman of the program committee of the Missouri State Medical Association; lieutenant colonel, medical reserve corps, U. S. Army, not on active duty; holder of the French Legion of Honor and the Croix de Guerre after four years of foreign service during World War I; on the consulting staff of the Ellis Fischel State Cancer Hospital, Columbia; on the staffs of St. Luke's Hospital, Kansas City General Hospital, Memorial Hospital, St. Joseph's Hospital and the Research Hospital, where he died April 30, aged 55, of coronary disease.

Joseph C. Dodds, Champaign, Ill.; Chicago Medical College, 1889; instrumental in founding and one of the original trustees of the Urbana and Champaign Sanitary District, serving on the board for many years; for many years a member and for ten years president of the Burnham Library board; for twelve years vice president of the Citizens State Bank; served on the staff of the State Hospital in Kankakee; district surgeon for the Illinois Central Railroad and for six years state medical director of the Modern Woodmen of America; superintendent and treasurer of the Twin City Ice and Cold Storage Company; died in the Burnham City Hospital, May 4, aged 80, of pneumonia.

Max William Alberts, St. Paul; University of Minnesota Medical School, Minneapolis, 1924; member of the American Medical Association; fellow of the American College of Surgeons; clinical assistant in surgery at his alma mater; recently elected first vice president of the Minnesota State Medical Association; served as president, vice president and secretary of the Minnesota State Board of Medical Examiners; served as vice president of the Minnesota Society for the Control of Cancer; attending surgeon, St. Joseph's, Charles T. Miller, Ancker and Children's hospitals and the Gillette State Hospital for Crippled Children; died June 11, aged 46, of coronary thrombosis.

Clare Fred Nesbitt Schram ⊕ Kingsport, Tenn.; Columbia University College of Physicians and Surgeons, New York, 1916; served as president and secretary of the Sullivan-Johnson Counties Medical Society; past president of the American Association of Industrial Physicians and Surgeons; medical director of the Tennessee Eastman Corporation and Holston Ordnance Works; for many years head of the medical department of Fairbanks, Morse and Company in Beloit, Wis.; treasurer of the Women's Field Army for Cancer Control; on the staff of the Holston Valley Community Hospital; died May 22, aged 61, of coronary thrombosis.

Ralph Beverley Ober ⊕ Springfield, Mass.; Harvard Medical School, Boston, 1901; specialist certified by the American Board of Surgery; member of the New England Surgical Society; fellow of the American College of Surgeons; served as a major in the medical corps of the U. S. Army during World War I; consulting surgeon and formerly president of the staff of the Springfield Hospital, where he served on the surgical staff for many years; for thirty-five years a member of the Massachusetts Mutual Life Insurance Company, serving as associate medical director; died in Sarasota, Fla., April 13, aged 66, of coronary thrombosis.

Roy Whittier Porteus ⊕ Bellefontaine, Ohio; Rush Medical College, Chicago, 1906; interned at St. Anne's and St. Elizabeth's hospitals in Chicago; served a residency at the Roselia Maternity Hospital and Foundling Asylum in Pittsburgh; clinical assistant, department of otology, rhinology and laryngology at his alma mater, 1913-1914; at one time fellow in rhinology and otolaryngology at the Mayo Clinic in Rochester, Minn.; retired member of the Illinois State Medical Society and member of the Association of Resident and Ex-Resident Physicians of the Mayo Clinic; died March 27, aged 63, of uremia and heart disease.

Russell Hall Birge ⊕ Cleveland; Harvard Medical School, Boston, 1898; assistant clinical professor of surgery at the Western Reserve University School of Medicine; fellow of the American College of Surgeons; served as chairman of the medical advisory board number 7 of the Selective Service and in the medical corps, U. S. Army, during World War I; past president of the Academy of Medicine of Cleveland and the Cleveland Medical Library Association; on the staff of the Lakeside Hospital, where he died May 16, aged 72, of dissecting and ruptured arteriosclerotic aneurysm of the abdominal aorta.

Edward Ackermann ⊕ Dover, N. J.; University and Bellevue Hospital Medical College, New York, 1909; died in the General Hospital April 4, aged 69, of peritonitis, gangrene of the bowel and mesenteric thrombosis.

William E. Alexander, Memphis, Mo.; University of Louisville (Ky.) Medical Department, 1894; died in St. Joseph's Hospital, Keokuk, Iowa, April 18, aged 72, of ruptured appendix.

Aaron Hirst Appel ⊕ Colonel, U. S. Army, retired, New York; Jefferson Medical College of Philadelphia, 1878; appointed an assistant surgeon in the U. S. Army in 1879; promoted to captain in 1884, major in 1897, lieutenant colonel in 1907 and colonel Jan. 28, 1910; retired June 6, 1911 at his own request after thirty years' service; returned to active duty from July 27, 1918 to July 10, 1919; died March 13, aged 88, of coronary thrombosis.

Bruce Elwyn Beeman ⊕ Lancaster, N. Y.; University of Buffalo School of Medicine, 1934; interned at the Millard Fillmore Hospital in Buffalo, where he served a residency in medicine and obstetrics; died April 27, aged 34, of chronic pulmonary tuberculosis and myocardial failure.

Allen Christopher Bradley, Bridgeport, Conn.; New York Homeopathic Medical College and Hospital, New York, 1901; served as a member of the Selective Service Appeals Board; died April 11, aged 69, of carcinoma of the prostate and hypertensive heart disease.

Maurice Joseph Butler, Newport, R. I.; College of Physicians and Surgeons, Baltimore, 1906; served as medical examiner for Newport County; local medical representative of the Veterans Bureau and a United States insurance examiner; died May 4, aged 61, of valvular heart disease and chronic *diffuse nephritis.*

Hugh Lester Charles ⊕ Atchison, Kan.; Chicago College of Medicine and Surgery, 1912; served in France during World War I; died April 13, aged 54, of coronary thrombosis.

Ugo A. D. Collelmo, Frontenac, Kan. (licensed in Kansas in 1907); honorary member of the Kansas Medical Society; member of the American Medical Association; died March 25, aged 78, of myocardial degeneration with cardiac thrombosis.

William Henry Conner, Batavia, N. Y.; Northwestern University Medical School, Chicago, 1907; served as passed assistant surgeon in the U. S. Public Health Service and on the staffs of various Veterans Administration facilities; major, medical reserve corps, U. S. Army, not on active duty; died April 28, aged 72, of coronary thrombosis.

Theodore W. Conzelman, St. Louis; Homeopathic Medical College of Missouri, St. Louis, 1883; died in St. Anthony's Hospital April 28, aged 82, of arteriosclerosis.

William Arnice Cotter, Ozark, Ala.; University of Louisville Medical Department, 1909; member of the American Medical Association; served as president of the Dale County Medical Society; died in the Moody Hospital, Dothan, April 3, aged 62, of heart disease.

Howard Hubbell Davis ⊕ Cleveland; Western Reserve University Medical Department, Cleveland, 1910; received the Distinguished Service Cross for extraordinary heroism under fire overseas during World War I; on the staff of the Grace Hospital, where he died May 28, aged 62, of cerebral hemorrhage.

Frances Dickinson ⊕ Chicago; Woman's Medical College, Chicago, 1883; served as dean and president of the Harvey Medical College; honorary trustee of the Chicago Academy of Science; emeritus member of the Illinois State Medical Society; died in Orange City, Fla., May 19, aged 89, of coronary thrombosis and arteriosclerosis.

William West Duckering, Boston; Harvard Medical School, Boston, 1898; member of the American Medical Association; formerly on the staff of the Boston Dispensary; died May 3, aged 83.

MAJOR LUTHER CALDWELL HEIDGER, M. C., A. U. S., 1897-1944

Ethelbert L. Elmore, Puxico, Mo.; Barnes Medical College, St. Louis, 1905; member of the American Medical Association; died in the Missouri Baptist Hospital, St. Louis, April 24, aged 71, of carcinoma of the liver.

Leon Felderman ⊕ Philadelphia; Medico-Chirurgical College of Philadelphia, 1911; formerly president of the North End Medical Society; a captain in the medical corps of the U. S. Army during World War I, serving overseas; during 1924-1925 surgeon general of the Veterans of Foreign Wars; in 1928 presented with the French Legion of Honor; served as chairman of the local draft board number 77 from its inception in 1940 until he recently resigned; on the staffs of many hospitals in Philadelphia; died May 14, aged 54, of coronary thrombosis.

Frederick Abraham P. Fetherolf ⊕ Allentown, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1902; fellow of the American College of Surgeons; served on the senior staff of the Allentown Hospital; died May 25, aged 64, of heart disease.

Warren Woden Foster ⊕ Washington, D. C.; Harvard Medical School, Boston, 1882; member of the Connecticut State Medical Society and the American Medical Association; served as medical examiner for the U. S. Bureau of Pensions; died in the Emergency Hospital May 3, aged 86, of annular carcinoma of the ascending colon.

Joseph R. Gaines, Las Animas, Colo.; St. Louis College of Physicians and Surgeons, 1891; member of the American Medical Association; for many years county physician; died April 30, aged 79, of carcinoma of the prostate.

CAPT. ADRIAN Z. LEON, M. C., A. U. S., 1911-1945

Boyd Emerson Gamble ⊕ Manchester, Pa.; Medico-Chirurgical College of Philadelphia, 1909; died March 30, aged 61, of carcinoma of the esophagus.

Arthur Harold Gaston, Mount Lebanon, Pa.; Cleveland Homeopathic Medical College, 1908; died in the Veterans Administration Facility, Aspinwall, February 13, aged 62, of pulmonary edema and hypertensive heart disease.

Harvey Landis Gerberich, Lebanon, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1906; died March 14, aged 72, of chronic sclerotic myocarditis.

William Hammond, Glen Olden, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1894; died in the Taylor Hospital, Ridley Park, May 15, aged 74, of injuries received in a fall.

KILLED IN ACTION

Luther Caldwell Heidger, Stratford, Conn.; University of Vermont College of Medicine, Burlington, 1921; member of the American Medical Association; interned at the Bridgeport Hospital in Bridgeport; in 1929 appointed medical examiner of Stratford; commissioned a captain in the Army of the United States (National Guard) on Sept. 16, 1940; his first assignment was at Fort H. G. Wright, New York, as medical officer of the 242d Coast Artillery; in February 1941, at his request, transferred to Randolph Field, Texas, to take a flight surgeon's course; sent to Jacksonville, Fla., and later to Albuquerque, N. M., where he was assigned to the 19th Bombardment Group and promoted to major; previously reported missing in action and believed to be a prisoner of the Japs; awarded the Distinguished Service Cross, Air Medal and the Purple Heart; killed in action in Mindanao, P. I., Sept. 7, 1944, aged 47.

Carlton Patrick Hogan, Burlington, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1930; member of the American Medical Association; commissioned a captain in the medical corps, Army of the United States, on July 3, 1942; killed in action in the European area Nov. 27, 1943, aged 39. [It has been impossible to obtain a photograph of Dr. Hogan.]

Adrian Zacharia Leon, New York; Université de Montpellier Faculté de Médecine, France, 1936; member of the American Medical Association, entered the medical corps, Army of the United States, as a first lieutenant on April 13, 1944; began active duty May 6, 1944; assigned to Brooke General Hospital, Fort Sam Houston, San Antonio, Texas; promoted to captain, a battalion surgeon serving with the Seventh Army; won the Bronze Star for "tirelessly and diligently treating the wounded under the most trying conditions", killed in action in Austria May 3, aged 33

Zed Thomas Hawkins, South Pasadena, Calif.; Eclectic Medical Institute, Cincinnati, 1893; member of the American Medical Association; honorary member of the Indiana State Medical Association; died April 26, aged 77, of heart disease.

George Burton Heinecke ⊕ Washington, D. C.; Columbian University Medical Department, Washington, 1892; at one time assistant demonstrator of anatomy at his alma mater, now known as the George Washington University School of Medicine; veteran of the Spanish-American War; for many years medical examiner for the Metropolitan Life Insurance Company and supervising medical inspector for the Royal Arcanum, a fraternal organization; died in the Emergency Hospital April 25, aged 73, of hypertensive heart disease.

Norris Cecil Hodge ⊕ Marianna, Ark.; University of Tennessee College of Medicine, Memphis, 1926; interned at the Memphis General Hospital, Memphis, Tenn.; secretary of the Lee County Medical Society; served as medical officer in the Arkansas National Guard; president of the Farmers and Merchants Bank of Marianna; died April 21, aged 45, of coronary thrombosis.

Ford W. Huff, Parsons, W. Va.; Maryland Medical College, Baltimore, 1904; died June 6, aged 67, of diabetes mellitus.

William Richard Janeway, Staten Island, N. Y.; Columbia University College of Physicians and Surgeons, New York 1907; member of the American Medical Association; past president of the Richmond County Medical Society; director of the New York Tuberculosis and Health Association for two years and chairman of the Staten Island Tuberculosis and Health Committee; interned at St. Luke's Hospital in New York; on the staff of the Staten Island Hospital; died June 16, aged 62, of cerebral hemorrhage.

MAJOR BENJAMIN RITTER, M. C., A. U. S., 1900-1945

Clara Lydia Kohls ⊕ San Francisco; University of California Medical School, San Francisco, 1927; died March 18, aged 48, of coronary occlusion.

Albert Arthur Krugg, Coffeyville, Kan.; Medico-Chirurgical College of Kansas City, Mo., 1898; member of the American Medical Association; served as a member of the city council and board of education; founder of the Coffeyville Hospital; author of "Facts and Fancies"; died February 17, aged 80, of diabetes mellitus.

Claud Armstrong Mathews, Austin, Texas; University of Texas School of Medicine, Galveston, 1911; member of the American Medical Association; examining physician for Selective Service Board number 3; on the staffs of St. David's Hospital, Seton Hospital and the Brackenridge Hospital, where he died April 10, aged 57, of subacute bacterial endocarditis.

Charles E. McClary, Syracuse, N. Y.; Rush Medical College, Chicago, 1886; member of the American Medical Association; on the staff of the Crouse-Irving Hospital; died March 6, aged 82, of coronary thrombosis and arteriosclerosis.

Henry Dudley Prescott, New Bedford, Mass.; Harvard Medical School, Boston, 1902; served on the staff of St. Luke's Hospital; fellow of the American College of Surgeons; died March 19, aged 68, of coronary occlusion.

Samuel I. Seidenberg, New York; University of Odessa Faculty of Medicine, Russia, 1910; member of the American Medical Association; resident in medicine at the Home and Hospital of the Daughters of Jacob, where he died February 4, aged 64, of cerebral thrombosis.

Sylvester Silburne Shannon ⊕ Crosby, Minn.; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1906; village health officer and school doctor; on the staff of the Miner's Hospital; died March 28, aged 62, of heart disease.

William Spencer Sharp ⊕ Mesa, Ariz.; Medical Department of Tulane University of Louisiana, New Orleans, 1907; on the staffs of the Good Samaritan and St. Joseph's hospitals, Phoenix, and the Southside District Hospital; died April 30, aged 65, of heart disease.

LIEUT. MARSHALL J. ROGERS (MC), U.S.N.R., 1916-1945

Jonathan Mather Stafford, Essex, N. Y.; University of Vermont College of Medicine, Burlington, 1896; member of the American Medical Association; since 1908 health officer of Essex and county coroner since 1938; attending physician, Essex County Home since 1908; died March 23, aged 75, of coronary occlusion.

Bernard LeRoy Towle ⊕ Pawtucket, R. I.; Medical School of Maine, Portland, 1897; died in the Memorial Hospital February 6, aged 68, of cerebral hemorrhage.

Arthur Francis Weston, Keene, N. H.; Boston University School of Medicine, 1903; on the staffs of the Malden (Mass.) and Westboro (Mass.) hospitals and the Elliot Community Hospital; died in the Boston City Hospital March 23, aged 72, of carcinoma of the esophagus and stomach.

Wright Charles Williams ⊕ Peoria, Ill.; Miami Medical College, Cincinnati, 1903; member of the American Academy of Ophthalmology and Otolaryngology; on the staff of the Methodist Hospital; died May 12, aged 64, of leukemia.

Earle Montgomery Young ⊕ Mitchell, S. D.; Rush Medical College, Chicago, 1912; died March 21, aged 57, of coronary occlusion.

Edmund Kostanty Zaworski, Cleveland; University of Wooster Medical Department, Cleveland, 1909; on the staff of St. Alexis Hospital, where he died April 9, aged 62.

KILLED IN ACTION

Benjamin Ritter ⊕ New York; Middlesex College of Medicine and Surgery, Cambridge, Mass., 1926; University and Bellevue Hospital Medical College, New York, 1931; interned at St. Joseph's Hospital and Dispensary in Pittsburgh and the Rockaway Reach Hospital and Dispensary in Rockaway Beach, N. Y.; associated with the Mount Sinai Hospital; entered the medical corps, Army of the United States, on Feb. 25, 1943, as a captain; began active duty in the same grade on March 12, 1943; attached to the Normandy Base Surgeon's Office; promoted to major; posthumously awarded the Purple Heart; had been overseas twenty-two months; killed in action in France March 9, aged 45.

Marshall Johnson Rogers, Rule, Texas, Baylor University College of Medicine, Dallas, 1942; entered the U. S. Navy as an assistant surgeon with the rank of lieutenant (jg) on June 25, 1942; served an internship at the Naval Hospital in Jacksonville, Fla., began active duty in the U. S. Naval Reserve with the same rank on July 26, 1943; promoted to lieutenant in July 1944, served sea duty for eighteen months; killed February 21 by Jap aerial attack off Iwo Jima, aged 28.

Correspondence

ARTIFICIAL KIDNEY

To the Editor:—Referring to the editorial "Artificial Kidney" in the May 26 issue of THE JOURNAL, I would like to note that effective dialysis of the blood can also be achieved by using the living serous membranes instead of a semipermeable pipe system.

I revived nephrectomized dogs in uremic coma by perfusing their abdominal cavity with Ringer's, saline or isotonic dextrose solution (*Mitt. a. d. Grenzgeb. d. Med. u. Chir.* **39**:391, 1926).

During a perfusion lasting four hours, 3.968 Gm. of nonprotein nitrogen could be recovered from the perfusing fluid, whereby the protein nitrogen level in the blood of the animal dropped from 217 mg. per hundred cubic centimeters to 121.8. This procedure could be repeated and the life of the animal thus prolonged.

The feasibility of my technic of dialysis has been corroborated since then by a number of investigators (Heusser and Werder in 1927, Engel and Kerekes in 1927, Curtis in 1929 and 1930 and Jeney in 1932).

I also showed that intraperitoneal dialysis of the blood can easily be performed on human patients in local anesthesia without discomfort (*Wien. klin. Wchnschr.* **47**:851 [July 6] 1934).

Intact blood circulation and intact peritoneal cavity both are essential requirements for success.

STEPHAN ROSENAK, M.D.,
Gastro-Enterology Research Laboratory,
Mount Sinai Hospital,
New York.

DERMATOPHYTOSIS AND ONYCHOMYCOSIS

To the Editor:—The review by Montgomery and Casper of dermatophytosis and onychomycosis (THE JOURNAL, May 12, p. 77), as do so many papers on this subject, gives one the impression that these fungous infections can be cured without unusual difficulty. One notes in the discussion, however, Dr. Montgomery's confession that "the majority of extensive cases (of Trichophyton purpureum infection) are arrested and not cured." Unfortunately it is by these rebellious and long-standing cases that therapeutic skill is measured. For this reason it may be desirable to direct attention to two methods of treatment not mentioned in Dr. Montgomery's paper.

The first of these is freezing of the affected skin areas with ethyl chloride (*South. M. J.* **23**:1128 [Dec.] 1930). This method of treatment is regarded by some competent authorities as "probably the most effective single therapeutic agent."

The second method deals with chronic (toe) onychomycosis of the T. purpureum type, in which the entire thickness of the nail, and characteristically the entire nail, is involved. In the period 1933-1939 it was the policy of the U. S. Public Health Service in Havana, Cuba, to prohibit entry into the United States of refugees harboring chronic fungous infection of this nature. To expedite the entry of these unhappy individuals, no effort was spared to effect a "cure." After a year or more of interest as consultant to the service, it became evident to me that not a single actual cure had been brought about by the methods advocated by Dr. Montgomery—that is, removal of all affected nail areas and the continuous application of the strongest possible antimycotic remedies. Simple nail avulsion had also failed signally. It did not matter what later might be applied to the nail bed, or in what concentration. Regenerating epithelium invariably sealed off the budding nail plate, isolating it from all topical applications. When the nail plate finally emerged, it was always infected with the original fungus.

Accordingly, an operation was derived which aimed at the permanent ablation of the seriously infected toe nails (*Am. J. Surg.* **27**:145 [Jan.] 1935). It was learned that sharp curettage of the radix could not be depended on to prevent nail regeneration. Saucerization of overlying soft tissue and careful electrocauterization or fulguration of the radix were found to be necessary. Functionally these nailless toes were unhandicapped, and the cosmetic results were an improvement. Healing time for great toes averaged two months. These cures were absolute, not relative. Relapsing epidermophytoses and epidermophytids of many years' duration were finally susceptible to actual cure.

In a large series of operations performed under procaine digital nerve block, no serious complications were witnessed. Security of the digital circulation should, of course be manifest for this simple and effective operation.

K. P. A. TAYLOR, M.D.,
Lieutenant Commander, U.S.N.R.,
Clearwater, Fla.

THE CONTROL OF SCHISTOSOMIASIS

To the Editor:—Thirty years' close study of the control of schistosomiasis in Africa forces me to the conclusion that the natural enemies of snail hosts such as water beetles, river crabs, birds and lizards should be preserved, that chemicals interfering with wild life along the course of rivers should be avoided and that the present attacks on the iguana by natives and others should be controlled.

A steady infection among the natives in spite of improved education in places where chemicals have been used either to destroy the snail hosts or for mosquito control shows the mistake of such official efforts and adds interest to the effectiveness of removing river rushes and treating native carriers in other districts. Further use might well be made of burning cane or covering in portions of polluted streams occasionally, in view of the importance of small and easily overlooked snail hosts.

Increased efforts to control schistosomiasis and allied infections are needed in view of the spread of store keepers whose religion includes no clear teaching in regard to safeguarding the health of others and who allow human excreta and contaminated water to enter flowing streams, where they serve as constant means of infecting the primitive races, who are wont to collect and use water from running streams without water purification and who get their feet and hands contaminated by the free swimming larval parasites.

F. GORDON CAWSTON, F. Z. S., Durban, South Africa.

GAMMA GLOBULIN

To the Editor:—Comment in an editorial on gamma globulin in THE JOURNAL, June 9 (p. 442), gives the impression that only until recently has the origin of the globulins remained uncertain. Yet numerous investigators in the last fifty-three years have held views similar to those expressed in the papers referred to and to which no reference is made. Schmidt in 1892 first suggested that leukocytes, chiefly lymphocytes, are the source of fibrinogen. Moll in 1903 also suggested that some globulins arose from leukocytes. Müller in 1905 ascribed the source of fibrinogen to the lymphoid tissue of the spleen and lymph nodes. These and other references on the subject can be found in a study on "The Origin of Blood Proteins" (*Folia haemat.* **52**:187, 1934) in which substances having properties of fibrinogen, globulin and albumin were recovered from disintegrated lymphocytes.

HOBART A. REIMANN, M.D., Philadelphia.

The opinions and views set forth in this communication are those of the writer and are not to be considered as reflecting the policies of the Navy Department.

POSTGRADUATE CONTINUATION COURSES FOR VETERAN AND CIVILIAN PHYSICIANS

Compiled by the Council on Medical Education and Hospitals for Period July 1, 1945 to Jan. 15, 1946

Medical schools, hospitals, state medical societies and other medical educational institutions and organizations are providing the Council with a growing body of information on courses designed primarily to meet the needs of returning medical officers. These have been incorporated into the lists on these pages. They are not specifically designated for veterans, since most if not all of them may also be open to interested civilian physicians. Furthermore, all courses listed which were not designed primarily for physician veterans are also open to qualified returning medical officers.

Postgraduate Continuation Courses for Practicing Physicians—July 1, 1945 to Jan. 15, 1946

Institution	Title of Course	Schedule of Course	Registration Fee and/or Tuition
ALLERGY (See also Dermatology and Syphilology)			
Cook County Graduate School of Medicine, 427 South Honore Street, Chicago 12	Allergy	1 month, monthly	$200
Harvard Medical School Courses for Graduates, 25 Shattuck Street, Boston, 15 At: Massachusetts General Hospital	Clinical Allergy	July 9 thr. 20, 1945 2 weeks	50
Long Island College of Medicine and the Medical Society of County of Kings and Academy of Medicine, Joint Committee on Postgraduate Education, 1313 Bedford Avenue, Brooklyn 2 At: Kings County Hospital	Allergy	Oct. 13, 1945 8 weekly sessions	20
American College of Physicians, 4200 Pine Street, Philadelphia 4 At: Roosevelt Hospital, New York	Allergy	Oct. 8 thr. 13, 1945 1 week	Members 20 Nonmembers 40
Columbia University Faculty of Medicine, 630 West 168th Street, New York At: Mount Sinai Hospital	Allergy in Relation to Internal Medicine	Oct. 22 thr. Dec. 14, 1945 8 weeks	60
	Allergy in Children	Oct. 26 thr. Dec. 14, 1945 8 weeks	25
Columbia University—At: New York Post-Graduate Medical School, 303 East 20th Street, New York 3	Allergy	Oct. 29, thr. Nov. 16, 1945 3 weeks, full time	200
	Allergy	Jan. 4 thr. Feb. 15, 1945 2 months, part time	25
	Symposium on Allergy	Jan. 7 thr. 11, 1946 5 days, full time	100
New York Medical College Flower and Fifth Avenue Hospitals, 1 East 105th Street, New York	Allergy	2 months, arranged	50
Vaughan Memorial Clinic, 201 West Franklin Street, Richmond, Va.	Fellowship in Allergy	6 months to 1 year, beginning Jan. 1 and July 1 each year	None
ANATOMY			
Cook County Graduate School of Medicine, 427 South Honore Street, Chicago 12	Surgical Anatomy on Cadaver	Oct. 8 thr. 20, 1945 2 weeks	125
New York Medical College Flower and Fifth Avenue Hospitals, 1 East 105th Street, New York	Applied Anatomy of the Head and Neck	160 hours, arranged	300
	Applied Anatomy of the Upper Extremity	60 hours, arranged	115
	Applied Anatomy of the Lower Extremity	60 hours, arranged	115
	Applied Anatomy of the Abdomen	130 hours, arranged	either sex 300 both sexes 500
	Applied Anatomy for the Orthopedic Surgeon	100 hours, arranged	275
	Applied Anatomy for the Anesthetist	100 hours, arranged	275
	Applied Anatomy of the Thorax	120 hours, arranged	275
	Applied Anatomy of the Urogenital System	160 hours, arranged	295
University of North Carolina School of Medicine, Chapel Hill, N. C.	Anatomy	Full time, quarterly	per quarter 100
ANESTHESIOLOGY (See also Anatomy and Obstetrics and Gynecology)			
University of Georgia School of Medicine, University Place, Augusta, Ga. At: University Hospital	General Anesthesia (Inhalation and Intravenous)	2 weeks, arranged, throughout year	150
	Regional Anesthesia	2 weeks, arranged, throughout year	150
Cook County Graduate School of Medicine, 427 South Honore Street, Chicago 12	Inhalation Anesthesia	1 month, every month	200
	Regional and Intravenous Anesthesia	2 weeks, every 2 weeks	150
Harvard Medical School Courses for Graduates, 25 Shattuck Street, Boston, 15 At: Boston City Hospital, Harvard Teaching Service, Faulkner Hospital	Clinical Anesthesia	Tentative—arranged, monthly	50

Postgraduate Continuation Courses for Practicing Physicians—July 1, 1945 to Jan. 15, 1946—Continued

Institution	Title of Course	Schedule of Course	Registration Fee and/or Tuition
ANESTHESIOLOGY—Continued			
University of Minnesota. At: University of Minnesota Center for Continuation Study, Minneapolis 14	Anesthesiology	3, 6, or 12 days, announced	$15, $25, $50
Columbia University Faculty of Medicine, 630 West 168th Street, New York At: Mount Sinai Hospital	Anesthesia: Diagnostic and Therapeutic Nerve Blocking	Oct. 23 to Nov. 23, 1945 4 weeks	50
Columbia University—At: New York Post-Graduate Medical School, 303 East 20th Street, New York 3	Anesthesia	Sept. 1945 thr. Jan. 15, 1946 2 weeks, full time	100
New York Polyclinic Medical School and Hospital, 345 West 50th Street, New York 19	Regional, Spinal, Etc., Anesthesia	3 months, full time, 1st of any month	300
	Regional Anesthesia	12 sessions, arranged	75
New York University College of Medicine, 477 First Avenue, New York At: Bellevue Hospital and University	Anesthesia	6 months, Fall and Spring	Phys. in Serv. ½ fee Fee not stated
	Anesthesia	6 months to 1 year. Fall and Spring	
ARTHRITIS			
Long Island College of Medicine and the Medical Society of County of Kings and Academy of Medicine, Joint Committee on Postgraduate Education, 1313 Bedford Avenue, Brooklyn 2 At: Jewish Hospital	Arthritis	Oct. 17, 1945 8 weekly sessions	20
Columbia University—At: New York Post-Graduate Medical School, 303 East 20th Street, New York 3	Arthritis and Allied Rheumatic Disorders	Oct. 22 thr. 26, 1945 5 days, full time	45
	Arthritis and Allied Rheumatic Disorders	Jan. 8 thr. Feb. 26, 1946 2 months, part time	45
New York University College of Medicine, 477 First Avenue, New York At: Bellevue Hospital	Arthritis and Rheumatic Disorders	6 weeks, 3 mornings a week every 6 weeks	100
University of Pennsylvania Graduate School of Medicine, 237 Medical Laboratories, Philadelphia At: Abington Memorial Hospital	Etiology, Pathology, Physiological Deviations and Treatment of Arthritis	Oct. thr. Dec. 1945 Thursday mornings	25
BACTERIOLOGY			
Columbia University—At: New York Post-Graduate Medical School, 303 East 20th Street, New York 3	Clinical Bacteriology and Serology	Jan. 2 thr. 31, 1946 1 month, part time	100
University of North Carolina School of Medicine, Chapel Hill, N. C.	Bacteriology	Full time, quarterly	per quarter 100
CARDIOVASCULAR DISEASES (See also Electrocardiography)			
California Heart Association, 277 Pine Street, San Francisco At: Los Angeles and San Francisco	Postgraduate Symposium in Cardiovascular Disease	Oct. 18 thr. 25, 1945 3 days in San Francisco 2 days in Los Angeles	10 to 15
American College of Physicians, 4200 Pine Street, Philadelphia 4 At: Massachusetts General Hospital, Boston	Recent Advances in the Diagnosis and Treatment of Cardiovascular Disease	Nov. 5 thr. 10, 1945 1 week	Members 20 Nonmembers 40 Phys. in Serv. Free
Harvard Medical School Courses for Graduates, 25 Shattuck Street, Boston, 15 At: Peter Bent Brigham Hospital, Boston	Modern Diagnosis and Treatment of Heart Disease	July 2 thr. 31, 1945 4 weeks, daily	150
Long Island College of Medicine and the Medical Society of County of Kings and Academy of Medicine, Joint Committee on Postgraduate Education, 1313 Bedford Avenue, Brooklyn 2 At: Israel Zion Hospital	Clinical Cardiology	Oct. 16, 1945 4 sessions—once a week	20
Columbia University Faculty of Medicine, 630 West 168th Street, New York At: Montefiore Hospital	Elementary Clinical Cardiology	Oct. 2 thr. Dec. 18, 1945 Tuesdays, 1 to 4 p. m.	50
	Advanced Clinical Cardiology	Jan. 8, thr. June 6, 1946 Tuesdays, 1 to 4 p. m.	100
	Supplementary Clinical Cardiology	Oct. 2 thr. Dec. 18, 1945 and Jan. 8 thr. March 19, 1946 Tuesdays, 1 to 4 p. m.	50

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Hospitals: Lease of Space and Facilities to Physicians on Percentage of Physicians' Net Income Not the Practice of Medicine by Hospital.—The Temple Sanitarium, a corporation for profit, contracted in 1923 with Dr. J. M. Woodson to convey to him a parcel of land on which he was to erect, at his expense, a building, a part of which he was to use as an eye, ear, nose and throat clinic and a part of which was to be used by the corporation for general hospital purposes. The corporation agreed to send to Woodson all of its patients needing his specialized services and to reimburse to him 33⅓ per cent of the cost of the land and building he erected. In turn, the corporation was to be entitled to receive one third of the net income from the operation of the clinic. The contract was to continue in force until 1933. Woodson received title to the land and erected a building thereon, which was used for the purposes contemplated in the contract. Thereafter the corporate name of the Temple Sanitarium was changed to Scott & White Hospital. Woodson died in 1930 and his two sons, Drs. W. B. and B. P. Woodson, succeeded to his interest, the corporation waiving an option in the original contract permitting it to terminate the contract on Woodson's death. When the original contract, as supplemented, terminated in 1933, it was renewed until 1943, with an additional proviso that the corporation should have the option either to extend for ten years that contract when it expired in 1943 or to purchase the interest of the Woodsons. Shortly before expiration of the contract the corporation served notice on the Woodsons of its intention to purchase their interest under the terms of the contract. The Woodsons refused to comply, and Dr. W. B. Woodson filed a suit for partition against his brother, Dr. B. P. Woodson, and the corporation, asserting that each of the parties owned an individual one-third interest in the property and the building erected thereon. After institution of suit the defendant, Dr. B. P. Woodson, conveyed his interest to the corporation. The trial court denied partition and decreed specific performance of the contract in favor of the corporation against Dr. W. B. Woodson, who then appealed to the court of civil appeals of Texas.

Among other things, the plaintiff, Dr. W. B. Woodson, contended that the contract under which the corporation asserted the right to acquire his interest in the property was illegal and void because the corporation was engaged in the practice of medicine and surgery. At the trial to show that the corporation was engaged in the practice of medicine the plaintiff offered evidence that the corporation had collected medical fees during the twenty years the contract was in force and that the corporation apparently had physicians in its employ on a salary basis in connection with other medical services rendered in the portion of the building used by the corporation. He also sought to introduce in evidence a statement of the assets, liabilities and net proceeds of the corporation from its activities during the twenty year period. The trial court, however, excluded this evidence and the appellate court held that it acted properly. The present suit, said the appellate court, involves a specific written contract pertaining only to one specialized type and character of the medical and hospital services apparently being offered in the building in question—that of eye, ear, nose and throat practice. Whether or not the contract in question is ultra vires and whether or not the corporation thereby became engaged in the practice of medicine must be determined, as far as the suit on the contract is concerned, from the terms of the contract itself. Evidence as to what other contracts the corporation may have made with other physicians, how it may have operated other services in connection with the hospital it operated, what it paid other physicians engaged in services distinct and apart from the eye, ear, nose and throat clinic, and what profits and losses it may have made or suffered from the operation of other services are not admissible to test the validity of the specific contract sued on. The contract, being specific in all its terms as to the rights and duties of the parties thereto, must be interpreted and its validity determined according to its own provisions and not by what other contracts with other physicians relating to other services may have been.

Having reached that conclusion, the court did not deem it necessary to determine what constitutes the practice of medicine by a corporation. A corporation organized for profit, said the court, cannot practice medicine or employ physicians as its agents to do so for it. Obviously, under the medical practice act of Texas, a license to practice medicine can be issued only to a natural person. It is not controverted that all persons engaged in the operation of the Woodson eye, ear, nose and throat clinic, under the contract, were licensed physicians, and it is clear that Woodson and his associates under that contract were neither employees nor agents of the corporation. They were more in the nature of independent contractors and the percentage of the net proceeds collected by them and paid to the corporation was rather in the nature of rentals and as compensation to the corporation for services it rendered to the Woodsons in sending to them its patients needing specialized treatment and for otherwise caring for such patients. It is not controverted that the Woodsons were entirely independent of the corporation as to diagnosis, treatment of patients and operations to be performed, using their own judgment. They fixed and collected their own fees, kept their own books and accepted full responsibility to their patients for the nature and character of their services, and an express provision in the contract held the corporation harmless against any action or claim that might be made against it growing out of malpractice, negligence, unskilled service or mistreatment of any patient, employee or visitor by persons connected with the clinic. In brief, the Woodsons retained specifically the same relationship with, and responsibility to, their patients, whether such patients came to them of their own accord or were sent by the corporation, that they would have maintained had the contract not been made and as if the Woodsons had operated their specialized clinic on their own responsibility. Under the circumstances we think it clear that the Woodsons did not act as agents or employees of the corporation, that their acts were not the acts of the corporation, and that the corporation as such was not engaged, as far as the contract is concerned, in practicing medicine through them as agents. The judgment of the court in effect permitted the corporation to compel the plaintiff to convey his interest in the property to the corporation.—*Woodson v. Scott & White Hospital, 186 S. W. (2d) 720 (Texas, 1945).*

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF INTERNAL MEDICINE: *Oral.* San Francisco, Oct. 15-17. *Written.* Various centers, Oct. 15. Final date for filing application is Aug. 1. Candidates in the armed forces may take the examination at their station with the permission of their medical commanding officer. Asst. Sec., Dr. W. A. Werrell, 1301 University Ave., Madison 5, Wis.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: Chicago, May 27. Final date for filing application is Jan. 31. Sec., Dr. P. C. Bucy, 912 S. Wood St., Chicago 12.

AMERICAN BOARD OF OPHTHALMOLOGY: Chicago, Oct. 4-6; and Los Angeles, January. Sec., Dr. S. Judd Beach, 56 Ivie Rd., Cape Cottage, Me.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: *Part I. Oral and Written.* New Orleans, Sept. 28-29, Philadelphia, Oct. 5-6, Chicago, Oct. 12-13 and San Francisco, Oct. 19-20. Final date for filing application is August 1. Sec., Dr. G. A. Caldwell, 3503 Prytania St., New Orleans 15.

AMERICAN BOARD OF OTOLARYNGOLOGY: Chicago, Oct. 3-6. Sec., Dr. Dean M. Lierle, University Hospital, Iowa City, Ia.

AMERICAN BOARD OF PEDIATRICS: *Written.* Locally, Oct. 19. *Oral* New York, Dec. 7-8. Sec., Dr. C. A. Aldrich, 115½ First Ave., S. W., Rochester, Minn.

AMERICAN BOARD OF RADIOLOGY: *Oral.* Fall, 1945. Final date for filing application is Aug. 1. Sec., Dr. B. R. Kirklin, Mayo Clinic, Rochester, Minn.

AMERICAN BOARD OF SURGERY: *Written.* Various centers, October 24. Final date for filing application is Aug. 1. Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia 2.

AMERICAN BOARD OF UROLOGY: *Written.* Chicago, Dec. 9. *Oral* Chicago, Feb. 19-22. Sec., Dr. Gilbert J. Thomas, 1409 Willow St., Minneapolis 4.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Alabama State Medical Assn. Journal, Montgomery

Intravenous Morphine. H. Smith and S. Schotz.—p. 265.
*Fox Rabies. H. N. Johnson.—p. 268.
Medical Practice of the Past. R. E. Hale.—p. 271.

Fox Rabies.—Johnson says that whenever fortuitous circumstances have allowed wild canine species such as the fox or coyote to become abundant in a region where rabies is enzootic in dogs there is a constant threat of a serious epizootic of rabies. The gray fox species has become unusually abundant in several of the Southern states. During the past seven years fox rabies has been reported in Alabama, Arkansas, California, Georgia, Illinois, Iowa, Indiana, Kansas, Kentucky, Louisiana, New York, Pennsylvania, North Carolina, South Carolina, Ohio, Tennessee, Texas, Virginia, West Virginia and Wisconsin. In certain areas where foxes were usually abundant true epizootics of rabies developed. In one county in which fox rabies was prevalent 2,900 dogs were vaccinated within a period of three weeks. Four dogs developed rabies after vaccination, all within a period of thirty days. It is probable that these dogs were exposed before vaccination. Fourteen foxes, later proved rabid, were killed by fox hounds which had been vaccinated, and none developed rabies. No further cases of rabies have developed among vaccinated dogs in this county. The author cites several other outbreaks of fox rabies. In most instances the actions of rabid foxes are quite characteristic. Foxes are normally timid and avoid human habitations; those killed while invading farm yards in daytime have consistently been proved rabid by laboratory examination. Of the fox specimens submitted to the Alabama State Health Department, 31 were reported positive for rabies in 1943 and 32 in 1944. Nine persons were known to have been bitten by rabid foxes in 1944. It is essential that action be taken to reduce the number of gray foxes in areas where rabies is present. It is not necessary or practical to attempt to exterminate foxes, but their number must be reduced to a level where contact infection from fox to fox will not be frequent enough to maintain rabies. For the protection of their dogs and of their sport, fox hunters should aid rather than oppose such control measures. It is important that the heads of foxes and other wild animals such as skunks and coyotes be sent to laboratories for examination, so that there will be definite evidence of the extent of the disease.

Mechanism of Desensitization in Allergy. H. A. Heise.—p. 77.

Annals of Internal Medicine, Lancaster, Pa.

22:475-638 (April) 1945

Treatment of Subacute Bacterial Endocarditis with Penicillin. J. E. Paulin and C. J. McLoughlin.—p. 475.
Inhalation of Penicillin Aerosol in Patients with Bronchial Asthma, Chronic Bronchitis, Bronchiectasis and Lung Abscess: Preliminary Report. A. L. Barach, F. H. Silberstein, E. T. Oppenheimer, T. Hunter and M. Soroka.—p. 485.
Penicillin Therapy at University of Minnesota Hospitals: 1942-1944. W. W. Spink and W. W. Hall.—p. 510.
Septic Pulmonary Infarction: Report of 8 Cases. H. H. Hussey and S. Katz.—p. 526.
Meningococcic Meningitis: Report of 165 Cases. A. H. Meyer.—p. 543.
*Infectious Mononucleosis: Study of 96 Cases. J. H. Press, E. L. Shlevin and A. P. Rosen.—p. 546.
Phlegmonous Gastritis as Manifestation of Sepsis. L. J. Sachs and A. Angrist.—p. 563.
Acute Plasma Cell Leukemia. L. M. Meyer, J. Halpern and F. N Ogden.—p. 585.

Infectious Mononucleosis.—Press and his associates report 96 consecutive sporadic cases of infectious mononucleosis observed at the Jewish Hospital of Brooklyn over a ten year period. Infectious mononucleosis is an acute benign infection of unknown etiology characterized by irregular fever, swelling of the lymph nodes, sore throat, splenomegaly and lymphocytosis with the presence of abnormal lymphocytes in the peripheral blood stream; the blood serum may contain antibodies against sheep erythrocytes in high titers. The disease has been described also under terms such as acute lymphadenosis with lymphocytosis, monocytic angina, lymphocytic angina, lymphatic reaction and glandular fever. Diagnosis of infectious mononucleosis is in order in the presence of a suspected clinical picture when the hematologic findings are positive. The blood smear has been the most constant and characteristic single laboratory feature in the recognition of this disease. A positive Paul-Bunnell test is strongly confirmatory, but its absence does not preclude the diagnosis. It is sometimes necessary to repeat this test before a positive reaction develops. Because of the extreme diversity of manifestations of infectious mononucleosis the diagnosis may go unrecognized unless the disease is borne in mind and appropriate laboratory procedures are carried out.

Lymphoid Hyperplasia of Nasopharynx: Study of 131 Autopsy Specimens. A. R. Hollender and P. B. Szanto.—p. 291.

Penicillin in Mastoiditis and Its Complications.—Infections of the mastoid and contiguous structures can be readily controlled by penicillin, provided the causative organisms are sensitive to the drug. Sterilization of the blood stream and control of spreading infections can be accomplished by systemic administration of penicillin, but surgical intervention is usually necessary to effect a cure. Local application of the drug has proved beneficial in the healing of persistently draining mastoid wounds. Putney reports 10 cases, among them 1 each of cerebellar abscess, epidural abscess, mastoiditis, thrombosis of the lateral sinus, petrositis and meningitis. Sulfonamide compounds were administered in 8 of the 10 cases without clearing the infection, but prompt response was obtained from treatment with penicillin. Penicillin in combination with adequate surgical intervention offers the most effective means of combating serious and life endangering otologic complications.

Sulfathiazole in Chewing Gum for Oropharyngeal Infections.—Fox and his collaborators point out that effective topical application of sulfonamides to diseased oropharyngeal tissues has been difficult because certain factors prevented the maintenance of a satisfactory concentration of the drug. The smooth oral mucosa is continually washed by saliva and does not lend itself favorably to treatment by powders, ointments or solutions. Beneficial results from the local application of sulfon-

amide drugs in the mouth have been reported, but they occurred in such areas as the alveolus of an extracted tooth or a cavity in the maxilla or mandible where the drug was sheltered from swallowing and salivary dilution The authors decided to use chewing gum as a vehicle On the basis of their studies on this medium, they arrive at the following conclusions 1 Chewing of gum appears to be a mouth cleansing process 2 From the standpoint of minimal systemic toxicity and maximal local antibacterial potency, sulfathiazole in chewing gum seems to be the preferable local chemotherapy for infections of oral and pharyngeal mucosa which are susceptible to sulfonamide compounds 3 Best clinical results are obtained in those conditions of the mouth and pharynx in which the beta hemolytic streptococcus is the preponderant etiologic organism

Bulletin of Johns Hopkins Hospital, Baltimore

*Multiple Congenital Arteriovenous Aneurysms in Pulmonary Circulation J H Sisson, G E Murphy and E V. Newman —p 93
*Sulfamerazine in Treatment of Pneumococcal Lobar Pneumonia Analysis of 292 Cases A Genecin R C Austrian and R A Nelson —p 112
*Therapeutic Value of Penicillin Applied Locally, Based on Experience with Crude Material in Variety of Infections A M Fisher —p 134

Multiple Congenital Arteriovenous Aneurysms in Pulmonary Circulation—Sisson and his associates present the history of a woman aged 45 who had multiple congenital arteriovenous aneurysms in the pulmonary circulation The diagnosis established by angiography was confirmed at necropsy The clinical picture of 6 cases is summarized The usual symptoms are weakness, faintness and dizziness, dyspnea, chest pain and hemoptysis The signs are cyanosis, clubbing of the fingers, often visible hemangiomas, bruit over the chest, polycythemia and x-ray evidence of a localized opacity in the lung The diagnosis can be established by angiography, but this procedure may be dangerous in a patient with a circulatory shunt from the right to the left side of the heart The authors' patient died twenty-five minutes after the injection of diodrast This substance should be approached with caution in cases of hypertensive cardiovascular disease Treatment planned for the woman was pneumonectomy This operation had been successfully performed in 2 cases

Sulfamerazine and Lobar Pneumonia—Genecin and his associates employed sulfamerazine either alone or in combination with antipneumococcus serum or penicillin in 292 cases and found it effective Sulfamerazine, when given in daily dosages as small as 3 Gm per day after initial larger doses, produces high and relatively stable blood levels which are adequate in most instances to control pneumococcic pneumonia Toxic reactions were observed in 10 6 per cent of the patients These reactions were of the type seen following sulfadiazine No instances of peripheral neuritis were observed A small group of patients with particularly severe pneumococcic pneumonia were treated with sulfamerazine and penicillin The results were very encouraging

Crude Penicillin Applied Locally.—Fisher treated 95 cases of various types of infections with crude penicillin locally The results were good in 63 per cent, indefinite in 24 per cent and poor in 13 per cent The lesions which have shown the best response were the more acute or subacute lesions in which the bacteria are superficial or chronic lesions following surgical drainage with removal of all dead tissue Local penicillin therapy is not recommended to the exclusion of other methods but can be employed successfully in conjunction with its parenteral administration, with local surgical measures or with other antibacterial agents

Effect of Soy Flour on Nutritive Value of White Bread—Volz and her associates state that the addition of 15 or 20 per cent of soy flour significantly improves the protein quality of bread, but the product is so different from white bread that it is not accepted by the average consumer Since 5 per cent of soy flour can be used without appreciably altering the appearance or flavor of white bread it seemed of interest to determine whether such an addition would improve the protein quality In a study on rats the authors found that the addition of 5 per cent soy flour significantly improves the growth promoting value of white bread which contains 3 per

cent of whole milk solids. White bread containing 3 per cent of milk solids gave 0.97 Gm. gain per gram of protein consumed and bread with 5 per cent soy flour, containing an equal amount of milk, 1.17 Gm.; this difference is significant. The biologic value of the protein of the white bread as determined by the Mitchell method was 43.3 as compared with 47.7 for the bread with 5 per cent soy flour.

Diagnosis of Bronchogenic Carcinoma.—Bloch and his associates say that, through routine chest fluoroscopy of all patients of the outpatient department of the University of Chicago Clinics, bronchogenic carcinoma in the early and nonsymptomatic stage, as well as advanced tumors unrelated to the patients' complaints, are found in appreciable numbers. The differential diagnosis in early cases is frequently difficult and cannot be established by the conservative methods of examination but only by surgical exploration. X-ray examination can never establish a definite differential diagnosis even in extensive involvements. Particular diagnostic difficulties are offered by excavated lesions which are not accessible to the bronchoscope. Extrapulmonary involvements and systemic disease frequently confuse and obscure the picture of carcinoma. The absence of tubercle bacilli from the sputum eliminated by excavating lesions is most significant in the diagnosis of neoplasm.

So-Called Bronchial Adenoma.—Graham and Womack stress that the so-called bronchial adenoma must be regarded as a potentially malignant tumor. Although it may pursue a nonmalignant course for many years, there always remains the possibility of the appearance of malignant qualities, such as invasion of neighboring structures, involvement of regional lymph nodes and the development of distant metastases. The authors cite a case in which there was a combined carcinoma and sarcoma with the presence of bone. The malignant transformation of both the epithelial and the connective tissue elements in this case seems to support the suggestion made by the authors in 1938 that a wide variety of tumors can be thought of as arising from a fetal bronchial bud which has failed either to develop normally or to atrophy. At that time they offered the conception that either the mesodermal or the entodermal elements could be the origin of later neoplastic growth which could include not only such recognized pulmonary tumors as chondroma, fibroma, lipoma and sarcoma but also the so-called adenoma, which is composed predominantly of entodermal or epithelial elements. It is rare, however, to find malignant transformation of the two elements in the same tumor. The presence of bone in this case, the authors feel, is in line with their conception that "mixed tumors" is a better designation for these tumors than "adenoma." The frequent inability to determine from a biopsy specimen whether or not the tumor has already become malignant makes the attempt at local removal through the bronchoscope both unwise and dangerous. Total pneumonectomy is the procedure of choice.

Hamartoma of Lung.—According to McDonald and his associates three benign pulmonary tumors, which were strikingly similar and unusual, were removed at the Mayo Clinic in the past three years. All tissues in these tumors corresponded with those found normally in the bronchi, although lacking in orderly arrangement. Such neoplasms are supposed to be the result of abnormal development of the bronchial anlage; therefore they have been called hamartomas (to fail, to err). This paper is based on a study of 23 cases of hamartoma of the lung. In 3 of these the tumor was removed surgically. In the remaining 20 cases the tumor was discovered at necropsy. The incidence of hamartoma of the lung in a consecutive series of 7,972 necropsies was 0.25 per cent. This tumor occurs more frequently than has been recognized. It is strictly benign and only occasionally causes symptoms. In most cases the diagnosis has to be made by roentgenographic examination. A hamartoma should be suspected in every case of solitary lesion of the lung. Frequently this tumor cannot be distinguished from other lesions of the lung until a specimen of the tumor is examined microscopically. Treatment consists in excision of the tumor. One should try to conserve as much pulmonary tissue as possible.

***Penicillin* in Bacterial Endocarditis.**—Meads and his associates present observations on 9 cases of subacute bacterial endocarditis caused by Streptococcus viridans and on 7 proved or probable cases of acute bacterial endocarditis due to other organisms, all of which were treated with sodium penicillin at the Boston City Hospital during 1944. In the 9 subacute cases the dose generally used was 25,000 units intramuscularly every two hours for two weeks. Seven of the patients are alive and have been free from evidences of active infection for one to eleven months. Two patients had recurrence of infection, 1 after four months and the other after only one month. It is not certain whether or not these recurrences represent reactivation of the original infection or reinfection. An additional fatal case of Streptococcus viridans endocarditis was treated. Improvement occurred in another extremely severe case with a characteristic clinical course of subacute bacterial endocarditis with multiple emboli, with survival three months after treatment, but no bacteria could be grown from the blood before penicillin was started. In the fatal cases heart failure resulted from extensive damage to cardiac structures. In the 7 cases of acute bacterial endocarditis small doses were generally used because of the greater susceptibility of the organisms. Three of these patients are living and well. The diagnosis in all the fatal cases was confirmed at necropsy but in those who survived it is only

highly probable. Heparin was used together with penicillin in 3 of the Streptococcus viridans cases and in 2 of those due to the pneumococcus. There appeared to be no benefit from this therapy to justify the additional effort and risk. Early and intensive treatment with penicillin maintained for an adequate period offers the best hope for recovery or arrest of infection in cases of subacute and acute bacterial endocarditis.

Surgical Treatment of Intracerebral Hematomas.—Hamby says that, while the more common types of intracranial hemorrhage are well known, spontaneous, limited, removable intracerebral hematomas are less familiar. He reports 16 cases of gross intracerebral hematomas that were drained. There were 14 recoveries and 2 deaths. Cases due to cranial injury with skull fracture have not been included in this series. One of the two deaths was due to massive pulmonary atelectasis and the other to a fatal recurrent hemorrhage from a ruptured aneurysm of a major cerebral vessel. Seven of the cases were associated with cerebral arterial disease and 5 with intracerebral neoplasms (3 metastatic, 1 meningioma and 1 astrocytoma). One case was proved and 3 were suspected to be due to ruptured aneurysms of the major blood vessels. One case was of delayed post-traumatic intracerebral hemorrhage.

Chronic Pericardial Effusion Following Roentgen Therapy.—Blumenfeld and Thomas report the history of a woman aged 53 who presented herself with masses in the left breast and axilla. She was given within four days three doses of x-rays totaling 600 roentgens to a field including the left breast and axilla, also a single dose of 300 roentgens to the posterior axilla. Several days later a radical mastectomy was done. During the operation the patient was exposed to a dose of approximately 3,600 roentgens in air for the purpose of "sterilizing" residual cancer cells at the operative site. The x-rays were directed into the open wound, which was then closed. She was discharged following an uneventful recovery. Several months later the patient complained of cough with s tightness in the left shoulder and pain down the left arm. X- examination showed a shadow interpreted as roentgen pneu nitis. Six months later she reported abdominal distress. I ing the succeeding year she lost 25 pounds (11 Kg.), and co and abdominal discomfort persisted. At the end of the year October 1941, exertion dyspnea was observed for the first ti All the symptoms persisted for the following two years, in February 1944 the patient reentered the hospital with sy toms of myocardial damage. She died several weeks la From the necropsy studies it was concluded that the rema able thickening of the pericardium was probably the result the unusually intense irradiation of this region at the time the left mastectomy. The mechanical interference with heart movement was the principal cause of circulatory fail and the final illness. The left lung was extensively collap presumably as a result of irradiation. The literature aboun with references to the changes in the myocardium followi irradiation, but heretofore only passing mention has been ma of the effects of irradiation on the pericardium. Massive irradi tion of the open thorax is not to be recommended.

Acute Pancreatitis.—Morton stresses that pancreatitis must be considered as a possibility in patients complaining of sudden severe epigastric pain. The serum amylase test is of greatest assistance in deciding whether the pancreas is involved. The test is easily carried out, is accurate and gives more important information than any of the routine laboratory tests. The author thinks that as long as surgeons operate without using the amylase test to help in their diagnosis there will be a mortality from acute edematous pancreatitis. Before the amylase

test was available and operation was necessary to decide the diagnosis, the author had 9 fatalities in 22 cases of pancreatitis. With the proper use of the amylase test he treated 29 cases of pancreatic edema without a death, not operating during the height of the reaction. There are two types of pancreatitis, acute edematous and pancreatic necrosis. Acute edematous pancreatitis can be diagnosed by the serum amylase test and the rapid improvement under conservative treatment. Pancreatic necrosis must be suspected when the patient fails to make improvement within a few days. In acute edematous pancreatitis operation should be deferred until the reaction has subsided. Acute edematous pancreatitis is followed frequently by chronic pancreatitis. Pancreatic necrosis is followed by abscess, diabetes and pseudocysts in some of those who survive. Conservative treatment of pancreatic necrosis or pancreatic abscess is disastrous. When either condition is suspected, operation is indicated. Biliary tract disease should be treated after an acute attack of pancreatitis if it has played a part in the onset. Any surgical manipulation about the lower end of the common duct or the head of the pancreas is likely to be followed by postoperative acute pancreatic edema. This can be demonstrated by the amylase test. There is a considerable danger of this in the resection of posterior duodenal ulcer perforating into the pancreas. It carries a mortality which should be taken into consideration in resections of duodenal ulcer.

Intrasternal Infusions and Transfusions.—Reich and his associates show that when shock is brought about by wounds, hemorrhage or burns there is usually urgent need for the parenteral administration of fluids. These fluids can usually be given by vein, but in some instances the veins are collapsed, thrombosed or absent or the vein areas are obliterated by wounds or burns. The bone marrow offers a ready channel for the administration of fluids in these cases. The present report is a study of the administration of various fluid mediums through the sternal marrow. The work was done on 35 patients in the general wards of a large city hospital. The authors conclude that intrasternal infusions of saline solution, glucose and plasma are practical, but the intrasternal transfusions of blood were unsuccessful. The sternal route is of great value in the treatment of shock.

Pressure Effects of Cervical and Normal First Rib.—Walshe and his associates present 5 cases of cervical and rudimentary first rib pressure. When an abnormal rib is present it is rarely the only relevant skeletal abnormality, for scoliosis and vertebral deformities are commonly associated with it. The bony abnormality consists of an abnormal upper thoracic outlet. This outlet is commonly asymmetrical and abnormally raised and tilted. The associated nervous and vascular symptoms are not accounted for by the abnormal rib alone, for there is evidence that the clavicle plays an important part in the compression of nerve roots and artery. The clavicle and the abnormal rib form the two arms of a vise in which these structures are compressed. This view does not exclude the role of a rib in exerting traction on and stretching and bending of the structures which cross it. Damage to the subclavian artery may lead to its aneurysmal dilatation, with or without the formation of clot within it. Thrombosis, when it occurs, leads to severe ischemia in the upper limb and sometimes to the production of emboli which lodge in the digital arteries and give rise to gangrenous patches, sometimes erroneously attributed to disorders of sympathetic innervation. Vascular symptoms in the upper limb are not due to disorders of sympathetic innervation but to mechanical interference with the blood flow through the subclavian artery. When symptoms of sympathetic paralysis occur, they are referable to the stellate ganglion. Of the components of the syndrome of a paralyzing lesion of this ganglion, Horner's oculopupillary syndrome is the most familiar. The factors leading to pressure symptoms affecting nerves and artery when no abnormal costal element is present, the so-called normal first rib and scalenus anticus syndromes, are discussed. Perhaps the essential factor is a dropping of the shoulder girdle. This leads to increased tension on nerve roots and subclavian artery and, by narrowing the space between first rib and clavicle, may lead to the compression of these structures by the clavicle during movements of the arm. The need for a more systematic x-ray study of the upper thoracic outlet in cases of suspected rib pressure is stressed.

Schizophrenia.—Stockings separates schizophrenic cases into two distinct groups: one which responds to anoxic shock and one which responds to insulin. The dysoxic type is distinguished by depression of mood, slowing of cerebration, apathy

and general underactivity; it includes psychotic depressions, paranoid schizophrenia, catatonic stupors, simple schizophrenia and some types of alcoholic hallucinosis without dementia. Anoxic shock appears to have a specific stimulating effect on these cases. The dysglycolytic type is distinguished by overactivity, elation, motor excitement and rich variety of bizarre delusions and hallucinations. It comprises the acute manias, hebephrenic and catatonic excitement and paraphrenias. Insulin appears to have a specific tranquilizing effect in these cases and influences the underlying thought disorder. In acute dysoxic cases, e. g. acute catatonic stupors, application once daily for the first five shocks is found to be the optimum frequency, followed by application on alternate days. In milder cases shock therapy on alternate days is usually sufficient. Remission is usually obtained after seven to ten shocks. In dysglycolytic cases a course of twenty comas is usually sufficient. Complete remission may be expected in 70 per cent of all cases, improvement in 15 per cent and failure in 15 per cent.

Intrahepatic and Extrahepatic Jaundice.—The response of the plasma prothrombin to intramuscular injections of 5 mg. of synthetic vitamin K has been shown to be of value in the differentiation between intrahepatic and extrahepatic jaundice. Stein reports observations on 27 new patients, bringing the total to 50 patients. He suggests that the test be called the "prothrombin response to vitamin K test." Of a total of 45 cases of jaundice (excluding 5 cases of hepatic cancer) the test was correct in 43 cases. In 21 cases of obstructive jaundice an effective response (prompt or delayed) was obtained in all; in 24 cases of hepatocellular jaundice an ineffective response (partial or complete) was obtained in 22. The method of performing the test and the interpretation of the results obtained are examined in the light of the work of other investigators, and special attention is drawn to the following points not stressed by others: 1. A satisfactory method for estimating plasma prothrombin must be used. 2. Parenteral administration of vitamin K, preferably in doses of 5 mg., should be used. 3. A fixed initial prothrombin level must be obtained before injecting vitamin K, in order to exclude a spontaneous rise in the prothrombin level, e. g. in cases of acute hepatitis during the recovery phase. 4. The test is of limited application, as it is of value only in cases of jaundice with an initially low prothrombin level—preferably with a prothrombin index of less than 75 per cent. Cases of combined intrahepatic and extrahepatic jaundice may lead to difficulties in interpretation, namely primary or secondary liver cancer with metastases in the portal glands, and biliary cirrhosis following long standing obstruction of the bile ducts. Except for these difficulties the test is of great value in differentiating between "medical" and "surgical" jaundice.

*Poliomyelitis of Pseudomyopathic Form. M. Gesteira.—p. 117.
Quinine Iodobismuthate in Therapy of Whooping Cough. G. O. de Paula Marques.—p. 139.

Pseudomyopathic Poliomyelitis.—According to Gesteira poliomyelitis of the pseudomyopathic type is characterized by sudden appearance of paralysis either after an infectious period typical for poliomyelitis or without such a period. Two or more members of the family become simultaneously ill, which is a rare occurrence in poliomyelitis. Early paralysis and consequent moderate atrophy are symmetrical and are regularly distributed in the proximal areas of the limbs, near the pelvic and scapulohumeral joints. There is a lordosis. The type of gait and posture is similar to that of myopathy. The hands become clawed or show a tendency to this deformity. In cases reported by the author the electrodiagnostic examination late in the course of the disease failed to show any reaction of degeneration, which suggests complete regression of paralysis.

Uncommon Forms of Encephalitis: Typhus Without Fever and With Fatal Encephalomeningitic Course; Transient Encephalomeningitis. L. M. Kugelmeier.—p. 372.

Widal Reaction in Bacillary Dysentery.—Schafer examined serums for the presence of agglutinins in 150 soldiers who were immunized against bacillary dysentery. The Widal reaction was negative in 85, or 56 per cent. Serums in another series of 150 soldiers in the fall of 1943 were negative for agglutinins in 120 cases, or 80 per cent. The Widal reaction does not appear to be a satisfactory test of the immunizing effect of dysentery vaccines. The percentage of cases with agglutinins present in the serum was the same in immunized as in the nonvaccinated soldiers. A positive Widal reaction in soldiers not suffering from bacillary dysentery is not to be considered the result of immunization but suggests the existence of a ubiquitous causative factor. Latent infection with dysentery bacilli can play an important part. Since 1941, when the incidence of bacillary dysentery reached its height in the army, there has been a constant decrease in acute cases of bacillary dysentery, which was paralleled by a similar decrease in latent cases. Mass immunization of soldiers who have gone through several seasons of dysentery is not so necessary as for troops which have been brought for the first time from base areas to the battle front. Some secondary reactions to immunization such as diarrhea and pain in the joints or extremities are to be considered as specific allergic reactions against dysentery bacilli antigens in immunized persons with a latent infection.

Exophthalmic Goiter After X-Ray Treatment.—A total of 79 goiter patients were observed from eight to eighteen years after they had undergone x-ray treatment. Of the 71 considered in this report, 8 were later subjected to surgical treatment; 7 died, 12 are ill and 44 are well. The cause of death was thyrotoxic crisis in 2 and cardiac insufficiency in 4 cases. Of the 12 patients who were not well, 3 had cardiac insufficiency, 8 had a relapse of hyperthyroidism and 1 had myxedema. Slightly less than two thirds of the patients recovered with x-ray treatment. Reports on surgical treatment of exophthalmic goiter indicate a higher percentage of recovery, and the results are more rapidly obtained. The argument that x-ray treatment has no case mortality holds good only with certain reservations, for during the protracted treatment the patients are apt to die from thyrotoxic crisis or from the heart lesion.

Excretion of Hormones in Women with Polyarthritis.—Studies were made on 116 women with chronic polyarthritis and on 43 women with various orthopedic diagnoses. Attention was given to the relations between sexual function and joint disorders and a close connection was observed. The author stresses the high incidence of ovarian insufficiency in women with polyarthritis but does not believe that the separation

cases of a menopausal arthralgic type is justified. The processes involved are complex, but it is probable that endocrine factors play an important role in the etiology of chronic polyarthritis.

Causation of Experimental Gastroprival Pellagra.—In studies on experimental endogenous gastroprival pellagra Petri and his associates attempted to elucidate the etiology by means of various elective resections of the digestive tract together with therapeutic experiments. The studies were made on dogs instead of pigs and revealed that vitamin B_6 is the only one of the B vitamins so far investigated by the authors (vitamin B_1, nicotinic acid and lactoflavin) which alone exerts a distinct therapeutic effect on experimental gastroprival pellagra; i. e., it exerts its effect independently of the stomach.

*Can Rheumatic Infection Be Influenced by Artificial Tropical Climate? G. Edström.—p. 376.

Protective Value of BCG Vaccination.—Birkhaug says that, since it has been proved that BCG vaccine is harmless, attention must be concentrated on finding the best method for its administration. On the basis of an extensive survey and investigations he concludes that BCG vaccination performed either by the intracutaneous or by the percutaneous (multiple puncture or scarification) methods produces in guinea pigs a significant resistance against a virulent tuberculous infection. The multiple puncture BCG vaccination method produces the most potent resistance in guinea pigs. In nearly 5,000 children and adults the multiple puncture method produced 98 per cent positive tuberculin reactions with 1 mg. of old tuberculin in two months. An automatic apparatus performs forty punctures with one stroke. This multiple puncture method rarely produces a permanent blemish.

Rheumatic Infection and Artificial Tropical Climate.—Edström says that in 1941 one of the wards in the rheumatism department of the Lund Hospital was reconstructed into a tropical chamber; the air of the room has been kept at a constant temperature of 89.6 F. and its humidity at 35 to 40 per cent, a relatively warm but dry tropical climate. The ward beds were occupied during the past two years by 7 patients with rheumatic fever and 8 with chronic rheumatic polyarthritis. Of the 7 patients with rheumatic fever 6 became entirely free from symptoms and capable of working; 1 died of sepsis after an acute tonsillitis. Of the 8 patients with chronic polyarthritis 4 have become symptom free and capable of working. Two patients improved temporarily. One patient with a juvenile arthritis of the Still's disease type improved very much during the first treatment but after return to his home had a relapse, which could not be influenced by renewed treatment in the tropical ward. In 1 case the treatment was broken off on account of a mental depression. In 11 of the cases cultures from the throat at the beginning of tropical ward treatment showed hemolytic streptococci. In 9 of these cases the cocci disappeared during the stay in the tropical ward.

Acta Radiologica, Stockholm

*Studies on Relapses in Carcinoma of Uterine Cervix. S. Hultberg. —p. 59.

Roentgen Treatment of Carcinoma of Breast.—Gylstorff-Petersen reviews 601 cases of mammary carcinoma treated at the Radium Center in Aarhus between 1924 and 1936. Grouped according to Steinthal's classification, 25 per cent were in stage I, 59 per cent in stage II and 16 per cent in stage III. The five year survival percentages for the three groups were 43, 27 and 4 per cent respectively. The first stage patients operated on had a five year survival percentage of 73. Of the 308 patients given postoperative roentgen treatment 37 per cent survived more than five years. The author thinks that preoperative roentgen treatment is to be preferred to the postoperative. Of 113 inoperable patients treated by irradiation for carcinoma of the breast, 6 per cent were alive after five years' observation. The average age of the patients was 53 years. The results of the treatment were considerably poorer for those between the ages of 25 and 39 than for the older ones.

Recurrences in Irradiated Cervical Carcinoma.—Hultberg investigated the incidence of recurrences following irradiation of cervical carcinoma at the Radiologic Clinic in Lund, Sweden. Of 535 women who received irradiation during the period between 1927 and 1939, 281 obtained primary cure, but 90 of these later had a recurrence. The author discusses the possibility of reducing the risks of recurrences by means of extirpation of the uterus following irradiation and reports the results obtained with 16 patients who were treated by surgical intervention following irradiation. Twelve of these patients are alive and free from symptoms three and eight years after the operation. The microscopic examination of the tissues removed at the operation revealed in 7 cases cancerous residues in the cervix. In the remaining 9 cases no evidence of cancer could be established. The author suggests that more patients with cervical carcinoma should be operated on following irradiation.

Metastatic Ovarian Cancer with Primary Tumors in Gastrointestinal Tract.—Winge discusses the structure and incidence of secondary carcinomas of the ovary in cases of primary tumors of the gastrointestinal tract. They are usually bilateral. The classic Krukenberg tumor contains abundant signet ring cells, but the lines of demarcation are vague. From 1937 to 1943 11 of these ovarian carcinomas, 1 a typical Krukenberg tumor, were seen in the Pathologic Institute of Bispebjerg Hospital, Copenhagen.

*Anemia in Infectious Diseases. S. Dahl.—p. 99.
Arthritis Deformans, Etiology and Treatment: II. Fractures and Arthrosis Deformans. I. Palmer.—p. 103.

Anemia in Infectious Diseases.—Dahl says that in uncomplicated infectious diseases secondary hypochromic anemia, probably due to iron deficiency, occurs in from one fifth to one third of the cases; it occurs in complicated scarlet fever in 62.5 per cent of the cases. During an infection, a rise in sedimentation rate usually coincides with a fall in the hemoglobin percentage, and vice versa. When the sedimentation rate and hemoglobin percentage seem unrelated there is no anemia but at most a lowered hemoglobin content due to the patient's confinement to bed. Treatment of the anemia during the infection is apparently ineffective; when the infection subsides there is spontaneous recovery from the anemia.

Book Notices

Doctors at War. Edited by Morris Fishbein, M.D., Editor of the Journal of the American Medical Association. Cloth. Price, $5. Pp. 418, with illustrations. New York: E. P. Dutton & Company, Inc., 1945.

In some indefinite future, after the termination of the global war, the official histories of the Medical Services to our Army, Navy and Air Force will no doubt appear. Detailed, official, all embracing histories are contemplated. Previous medical histories of our wars repose on the shelves of the important libraries of the country, where they are consulted by specialists. Seldom are they perused by the doctor and probably rarely by any layman. For this reason "Doctors at War" is both timely and unique. The entire amazing story of the Medical Services to the Army, Navy, Air Force, industry and the civilian population is told here in a single volume by men who were largely responsible for the organization and the performance of the most gigantic task the medical profession of this country has ever been called to perform. Although dedicated to "the One Hundred and Eighty-Six Thousand Physicians of Our Country" it is written in a manner readily comprehended by the average reader. The volume was conceived, organized and edited by the veteran medical editor Morris Fishbein, who as chairman of the Committee on Information, Division of Medical Sciences, of the National Research Council came in contact almost daily with the various organizational phases of that task.

In the introductory chapter Dr. Fishbein presents a general outline and the scope of the task. The comparative figures compiled by Brig. Gen. Hugh Morgan speak for themselves. Thus, while the death rate in wounded in World War I amounted to 8.1 per cent it is only 3.3 per cent in World War II; meningitis mortality was 38 per cent in World War I and 4 per cent in World War II. The figures for pneumonia mortality were 28 per cent in World War I and 0.7 per cent in World War II. The annual death rate per thousand for all diseases in the Army, excluding surgical conditions, amounted to 15.6 per cent in World War I and 0.6 per cent in World War II. In the succeeding fifteen chapters the reader is privileged to follow step by step the history of the organization and the development of the medical units, the exciting recital of the heroic deeds on the battle front, the story of the important achievements and advances of preventive medicine, of the excellent work by the American surgeons working not infrequently under the very enemy fire.

Col. Leonard G. Rowntree, in the chapter "Fit to Fight," states that "war is a hard taskmaster but a great teacher. Medicine has learned much of the nation's strength, its steadfastness of purpose, its will to do, to win, to live and to be great and free. But it has learned also of the innumerable physical and mental defects, disabilities, disorders and diseases that now beset us. Let us hope that the lessons learned will not only have helped this nation to win the war but will also make us stronger and more productive in the postwar era."

The application of the newer knowledge in preventive medicine was made possible, according to Brig. Gen. James Stevens Simmons, by the combined efforts of the National Research Council, the Committee on Medical Research, the United States Public Health Service, the Bureau of Medicine and Surgery of the Navy, the Pan American Sanitary Bureau, the United States Department of Agriculture, the Coordinator of Inter-American Affairs, the American Red Cross, the International Health Division of the Rockefeller Foundation and most of the scientific institutions and societies in the fields of biology, medicine and public health. Problems investigated were those of nutrition, sanitation, protection against various infectious diseases in all the countries where American troops might be stationed, the Army's immunization and control of venereal disease, gastrointestinal diseases, the insect borne diseases and, in particular, malaria. Many of these problems were taken to the Division of Medical Sciences of the National Research Council and to the Committee on Medical Research of the Office of Scientific Research and Development, which arranged for the necessary investigations. The actual studies have been conducted by civilian doctors and scientists in the various laboratories and institutions of the country. The Committee on Medical Research has authorized, financed and supervised many projects for the Medical Department and has spent several million dollars in the search for answers to our problems. There have been hundreds of research projects dealing with different aspects of a wide variety of subjects, which include the control of infectious diseases, the discovery of new prophylactic and therapeutic agents against malaria and other tropical diseases, the discovery of effective insecticides and insect repellents, nutrition, fundamental studies of fitness and fatigue, transfusions and blood substitutes, shock, surgery, neuropsychiatry and aviation medicine. Extensive medical research is also being carried on through the Board for the Control of Epidemics, the Army Medical School and various laboratory and field installations of the Army.

Destruction of lice and the control of epidemic typhus became possible because of methyl bromide gas and the sensational new insecticide DDT. A striking example of the efficiency of the latter was demonstrated in Naples, when some two million civilians were deloused within a period of two months, thus checking the spread of epidemic typhus.

The low mortality of our wounded, we are told by Brig. Gen. Fred W. Rankin, was due to prompt surgical care by highly skilled specialists. It was made possible by a combination of two factors—the plan of medical service in the combat zone and the availability and proper utilization of young, formally trained medical officers. The plan of medical care in advanced battle zones was based on the principle that the sooner the wounded man receives adequate aid and subsequent definitive surgery, the more successful are the results. In addition, the full use of certain modern developments in medical therapy has played an important role in the establishment of that record. Among the most important of these are blood plasma and blood transfusion in the control of shock, chemotherapeutic agents such as the sulfonamides and penicillin in combating infection, newer methods in repair of injured nerves and defects of the skull and the treatment of chest wounds, abdominal wounds vascular injuries and the like. On reading this brilliant account one cannot but agree with Major Gen. Paul R. Hawley that our army has the finest medical service of any army in the world. The cream of the American medical profession serve with our forces, and aiding them is a group of consultants, nationally known specialists in their own fields.

Dr. Thomas Parran contributes a most informative chapter on the work of the United States Public Health Service. On that service rests the prevention of epidemic disease, the control of venereal disease in and around the camps, the prevention of industrial disease and the assurance of the health of the American people.

Aviation medicine is practically a new branch. The story of how the flight surgeons "kept them flying" is told in a chapter by Major Gen. David N. W. Grant.

The performance of the gigantic task described in this interesting volume is summarized in the last chapter, on the streamlining of the medical research for war by the National Research Council for War.

The book is timely in that it presents in one volume all the exciting information that has appeared in bits in the various periodicals, both medical and lay, and because of useful information on the many civilian and governmental activities which all add up in attaining the victory over a powerful enemy.

Radiologic Examination of the Small Intestine. By Ross Golden, M.D., Professor of Radiology, College of Physicians and Surgeons, Columbia University, New York. Fabrikoid. Price, $6. Pp. 239, with 75 illustrations. Philadelphia, London & Montreal: J. B. Lippincott Company, 1945.

The author introduces this subject with a brief outline of the indications for a radiologic study of the small intestine, a description of his method for carrying out this detailed study and discussion of the use of the small intestinal enema (Schatzki). There follows an account of the known facts of developmental anatomy of the small intestine graphically clarified by four excellent diagrammatic drawings of the stages of rotation of the intestine. He then describes the gross and microscopic anatomy of the small intestine, following with a clear presentation of the present knowledge of the physiology of the various components of the intestinal wall, including a discussion of the intrinsic nervous plexuses, the muscularis

mucosae and the chemical mediator theory of the neuromuscular and neuroepithelial mechanism of the intestine.

A chapter is devoted to the normal radiologic appearances of the adult small intestine from the standpoint of motility and mucosal relief patterns. Of particular interest is the description of the independent motion of the mucosa illustrated by reproductions of roentgenograms showing normal changes in size, shape and direction of the mucosal folds. The author then describes briefly the physiology of the infant's small intestine, pointing out that the segmentation of the barium-containing intestine and the paucity of well developed mucosal folds may be due to a lag in the development of nervous control generally characteristic of the infantile state, improving as reflexes change and develop until the familiar adult type of motor activity and mucosal pattern occur.

Following chapters on peritoneal adhesions and ileus with special mention of the role of hypoproteinemia in the production of ileus and detailed description of the indications for and use of the Miller-Abbott tube in the diagnosis and treatment of ileus, the author launches into a discussion of the alterations in the appearances of the small intestine in primary and secondary nutritional disorders. He describes the variable clinical, radiologic and pathologic manifestations of these disorders and illustrates his text with reproductions of films and photomicrographs of the small intestine from cases of advanced nutritional disorders. He emphasizes the nonspecific nature of the radiologic findings, showing that they may occur in varying forms both in neurogenic states and in organic disease. The clinical improvement obtained by appropriate vitamin therapy and other nutritional measures in primary and secondary deficiency states is correlated with illustrative radiologic studies of cases showing partial or complete restoration of normal small intestinal motor function and mucosal pattern. Sclerosing mesenteritis and other diseases of the mesentery are discussed in relation to nutritional disorders.

In regard to intestinal allergy the author describes provocatively tested cases, but he concludes that "a diagnosis of intestinal allergy cannot be made on the basis of the roentgen examination alone at the present time."

Regional enteritis and tuberculous enteritis are discussed and illustrated, emphasis being placed on the use of pressure films for demonstration of mucosal abnormalities of the terminal ileum.

Illustrations of benign tumors, intrinsic and extrinsic malignant epithelial neoplasms of the small intestine, and lymphosarcoma of the small intestine are taken from the radiologic and pathologic findings of appropriate cases.

Developmental anomalies and defects, both of the small intestine and of the peritoneum (volvulus, atresias, duplications of the intestine, multiple diaphragms, internal hernia and Meckel's diverticulum) are discussed, and several of these are illustrated with reproductions of x-ray films. Similar treatment is given by the author to the effects of foods, drugs and emotion on the small intestine as well as the effects of various parasitic disorders, particularly amebiasis.

The text is further enriched by illustrative radiologic findings in unusual conditions, such as simple ulcer of the ileum, enlargement of the ileocecal valve, amyloidosis of the intestine and cathartic abuse. The concluding paragraphs are devoted to a discussion of the unexplained findings of Hale and Schatzki in the small intestine of patients with scleroderma.

This book is a valuable contribution to the literature on intestinal radiology and warrants well the attention of the radiologist, the internist and the abdominal surgeon. The author's style is clear and concise, the illustrations are well reproduced and the entire content is well indexed for ready reference. The book is documented by an extensive bibliography, which is as much a commentary on the author's approach to this subject as his thorough painstaking method of radiologic examination of the small intestine.

Special Diet Manual: Diet Lists. Paper. Battle Creek, Mich.: Kellogg Company. [n. d.]

This "manual" consists of a large folder, on the leaves of which are printed lists of foods commonly used in the various types of special diets. Included among the diets is one for use in allergy to egg, wheat and milk and others designated salt free, high and low residue and high iron, as well as light, soft and liquid diets. The principles of high vitamin and diabetic diets are given. In another section foods are tabulated according to increasing carbohydrate content. The folder contains a large pad of printed sheets on which are listed a great number of foods with the caloric value of their average servings. It is intended that these sheets be marked by the doctor and given to the patient as a diet list. Their usefulness in this way is questioned because of the time required to search through the lists for the foods desired and more particularly because of the lack of personalization which is generally desired. This material can be recommended as best suited for quick reference on special dietary treatment and food values.

Casualty Work for Advanced First-Aid Students. By A. W. MacQuarrie, M.B., Ch.B. Cloth. Price, $1.80. Pp. 231, with 41 illustrations. Philadelphia: Peter-Reilly Company; Edinburgh: E. & S. Livingstone, Ltd., 1944.

The methods described in this convenient pocket book were developed to meet "blitz" conditions endured by the civilian population of Great Britain. While these methods differ somewhat from those taught in the usual first aid courses, their basic principles are the same. They presuppose a sound knowledge of anatomy and physiology and experience in first aid work. Emphasis is placed on (1) immediate control of hemorrhage, (2) immobilization of all badly damaged tissues and (3) rapidity of delivery to the care of the surgeon.

The book can hardly be recommended as a continuation of the first aid course taught in this country, but it may be useful to specially trained rescue squads of fire and police departments and of hazardous industries. Certainly one would not trust the administration of morphine and nikethamide to the layman even though the "dosage is regulated by the medical officer" except in unusual situations in which relief, in the absence of surgical aid, is imperative. Nor is any good purpose served by advising that if whole blood or plasma is not available when needed "a fluid such as glucose gum saline solution may be used." Differential diagnosis is encouraged probably too much—to distinguish between genuine shock and hysteria in the midst of disaster may baffle even the ablest surgeon; and it hardly seems appropriate to explain the difference between cerebral hemorrhage, embolism and thrombosis.

Original and doubtless of great value to rescue squads is the section on transportation of injured persons. The diagrams are simple and clear. There is a good index. An amusing English idiom is the advice to begin the feeding of a starved person "with fluids and slops."

On Modern Syphilotherapy with Particular Reference to Salvarsan. By Albert Neisser. [Sammlung zwangloser Abhandlungen aus dem Gebiete der Dermatologie, der Syphilologie und der Krankheiten des Urogenitalapparates, Band I, Heft 1, 1911.] Translated by Isabelle von Sazenhofen Wartenberg. Biography and Bibliography by Frances Tomlinson Gardner. Reprinted from Bulletin of the History of Medicine, Volume XVI, Number 5, December, 1944. Boards. Price, $1. Pp. 42, with portrait. Baltimore: Johns Hopkins Press, 1945.

This interesting volume is reprinted from the *Bulletin of the History of Medicine* (**16**:469 [Dec.] 1944). Our California colleagues deserve sincere appreciation for emphasizing Neisser's contributions to venereal disease control, not only with relation to gonorrhea, but also of practical advantage still in syphilis.

Albert Neisser (1855-1916) was born near Breslau, where he took his degree in medicine in 1877. Two years later in Simon's Dermatology Clinic he had isolated the micrococcus of gonorrhea, which he named the gonococcus in 1882, when he became head of the Polyclinic. After work with leprosy he became interested in syphilis and went to Java to study the experimental disease in monkeys. Here he discovered the responsible organism but had been anticipated by Schaudinn at home. In 1907 Neisser joined Wassermann in studying an application of the serum complement reaction to the diagnosis of syphilis. In 1909 Neisser worked with Ehrlich. The present contribution, first given in 1911, is the result of this clinical experience with syphilis. In 1912 Neisser fractured his hip and later developed diabetes, from which he died. As Mrs. Gardner says, "It was Neisser's fate to perform too well too soon." His 141 contributions, in German, French, and English, are testimony to his professional devotion.

Mrs. Wartenberg's translation is clear and well worth reading by all interested in modern methods of syphilotherapy. Neisser insists on "energetic treatment in the period immediately following infection." Neisser claims to have proved that mercury is a spirocheticide. Accordingly, he insists on using mercurial preparations in conjunction with the new organic arsenicals, in particular arsphenamine as introduced by Ehrlich. He discusses toxic reactions to arsphenamine, with particular reference to nerve injury. Neisser offers a detailed discussion of his technic for treatment and emphasizes "several courses of treatment throughout three or four years, whether or not there are any symptoms."

Were Neisser still alive, he would undoubtedly be showing enthusiasm now for "rapid treatment methods." He would probably reach the same conclusion as he did in 1911: "Human indolence and stupidity will arrange that syphilis will never die out but will remain always a dangerous disease, but we know that new and wonderful weapons have been placed in our hands to combat it."

Dietética infantil. I: Alimentación del niño sano. II: Alimentación del niño enfermo. Por el Dr. José Espinasa Masagué. Monografías médicas "Balmis," 13. Paper. Price, 12 pesos per set. Pp. 191; 319. Mexico, D. F.: Compañía General Editora, 1944.

This book, in two volumes, is one of the "Monografías Médicas Balmis." It is an outline of the modern conceptions on dietetics of newborn infants and infants, with advice for the selection of proper food in accordance with the age of the infant and his condition either normal or in the course of diseases. The first book contains an introductory chapter on food and its constituents. The subject of vitamins is well discussed. In the other four chapters of the book the author deals with lactation, either natural or artificial, food after weaning, and technic in feeding normal infants. There are several tables with equivalents of food and formulas for preparation of artificial feeding and of food after weaning. In the second volume the author discusses infant feeding of premature infants and of infants either with abnormalities of the lips or normal but in the course of various diseases, especially diarrhea, gastric, cardiac and urinary diseases, acute and subacute infections, typhoid, anemia, convulsions and avitaminosis. The book is of value for physicians early in their building up of a pediatric clientele.

Nutrition with Sense. By Eleanora Sense. Cloth. Price, $2. Pp. 222, with illustrations by the author. New York: M. Barrows & Company, Inc., 1944.

In this compact little book much useful information and advice are found. The author covers nutrition from all aspects important to the householder. The early chapters provide simple accurate discussion of such fundamentals of nutrition as the place and function of carbohydrates, fats, proteins, vitamins and minerals in the diet. These terms are translated into foods as eaten, and up to date information is given on the effects of preparing and cooking. The nutritional facts throughout are presented simply and accurately. Problems of buying foods and their preparation for the table are considered, with rules for the proper cooking of various types of foods. Weekly menus are suggested for different seasons of the year, and a large portion of the book is devoted to recipes and directions for cooking. A limited number of tables giving nutritional value of foods are found at the end of the book. The criticism is made that in some instances the author goes beyond the bounds of normal nutrition by discussing nutritional therapy of disease conditions. This is scarcely warranted in this type of book. Otherwise the presentation can be recommended as excellent in outlining the facts of nutrition and guiding the student or housewife in the attainment of good nutrition.

The Examination of Reflexes: A Simplification. By Robert Wartenberg, M.D. Foreword by Foster Kennedy, M.D. Cloth. Price, $2.50. Pp. 222, with 7 illustrations. Chicago: Year Book Publishers, Inc., 1945.

At last the long awaited clarification of clinical reflexes has been achieved by a student of the nervous system. The multiplicity of reflexes named after their discoverers and rediscoverers and the confusion of a welter of classifications of reflexes has for too long been accepted uncritically. The author cuts through authoritative tradition and states a few unquestionable principles of reflex action. He then describes simply and accurately each clinical reflex and discards the accumulated junk of terminology based on different points of elicitation of the same reflex and the vanity of "discoverers." He ends his task with a simple but often unheeded statement: "Each new observation in clinical neurology should be subjected to a strict physiological interpretation." The book contains 465 references in the bibliography and detailed subject and author indexes. The book represents a vast store of knowledge based on clinical experience and a painstaking perusal of the literature. Its contents are based on sound physiology and should be carefully studied by all neurologists. The volume is a much better reference work for students of reflexes than most textbooks that have uncritically handed down errors from their precursors. It is a refreshing monograph and is highly recommended.

The New York Hospital: A History of the Psychiatric Service 1771-1936. By William Logie Russell. Cloth. Price, $7.50. Pp. 556, with illustrations. New York: Columbia University Press, 1945.

This book tells an interesting story of the psychiatric service in New York from 1771 to 1936, starting with an account of the earliest provisions for the treatment of the mentally ill in the state of New York. The story gradually develops into the building of the first hospital with its department of psychiatry, then the founding of the Bloomingdale Asylum, the state supervision and law, followed by the expansion of modern scientific psychiatry at Bloomingdale. This book is one of the best of its kind. It should be purchased by every psychiatrist, neurologist, psychiatric nurse and social worker. It will serve as an excellent guide regarding the various problems of mental illness as well as an excellent reference work for teaching.

The Human Body. By Logan Clendening, M.D. Fourth edition. Cloth. Price, $4. Pp. 443, with 106 illustrations by W. C. Shepard and Dale Beronius and from photographs. New York: Alfred A. Knopf, 1945.

The Human Mind. By Karl A. Menninger. Third edition. Cloth. Price, $5. Pp. 517, with illustrations. New York: Alfred A. Knopf, 1945.

These two books have been among the most successful of their type, having been purchased by many thousands, if not hundreds of thousands, of people. Dr. Clendening was able to revise his book before his untimely death, thus making a good book even better. Dr. Menninger has prepared a complete revision of his book with the assistance of many of his associates. It is an interesting work, adapted to persons preferably above high school age. The advances in psychiatry resulting from the extensive experience of the war have been incorporated.

The Neurologist's Point of View: Essays on Psychiatric and Other Subjects. By I. S. Wechsler, M.D. Cloth. Price, $3. Pp. 251. New York: L. B. Fischer, 1945.

Many of the chapters of this book have appeared in other publications, some quite outside the field of medicine, like the Menorah *Journal*. The author's interests extend from the neuropsychiatric problems peculiar to the Jewish people to the eternal conflict between the individual and society. There is a striking chapter on Sigmund Freud, with the conclusion that psychoanalysis will be remembered longest for the insight into normal and abnormal behavior which it has vouchsafed. A chapter entitled "A Brief History of Psychiatry" indicates a belief in a lessened incidence of hysteria and the opinion that the neuroses now develop on a higher psychic level than formerly because of changes in social and cultural conditions.

Poet Physicians: An Anthology of Medical Poetry Written by Physicians. Compiled by Mary Lou McDonough. Cloth. Price, $5. Pp. 210. Springfield, Illinois: Charles C Thomas, 1945.

Here are collected a variety of poems of interest to physicians and all of them by physicians. There are brief biographies of each of the poets concerned. The poems have been chosen largely for their medical flavor, although many physicians have written poetry quite outside the field of medicine. Such distinguished names as those of Sir Henry Head, Havelock Ellis, Sherrington, Oliver Wendell Holmes, Keats and Percival, the British laureate Robert Bridges and the immortal John McCrae set the tone of the entire volume. The book is supplemented by a cumulative index of poet physicians, some of whom might better be characterized simply as rhymsters. The book is a valuable addition to literary medicine.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

ANOCIASSOCIATION AND TREATMENT OF SHOCK

To the Editor:—I would greatly appreciate obtaining an authoritative appraisal of the work of the late Dr. George Crile as embodied in his book "Anoci-Association." Certain views were originally challenged by Dr. Cannon, yet I have the impression that theories on shock and management by transfusion are essentially original with Dr. Crile and that his work is being sustained. Modern writers do not seem to quote the contributions of Dr. Crile, and it was somewhat of a surprise to note that a recent article by Dr. Phemister in THE JOURNAL discussed at length the nociceptor mechanism. George F. Fasting, M.D., New Orleans.

ANSWER.—Crile and Lower in their book entitled "Anoci-Association," published in 1914, make the following statements: "From all of these observations we concluded that the ideal treatment [of shock] would be to fill the blood vessels with some fluid which would not pass through the vessel walls, would cause no chemical injury, would carry oxygen, and would always be immediately available. Human blood is the only fluid which possesses all of these qualifications." The experimental research referred to was first reported in the *Boston Medical and Surgical Journal* in 1908 (**158**:961). The experimental details were published in Crile's book "Hemorrhage and Transfusion" in 1909. In this book it is concluded that "transfusion is a better form of treatment for shock alone, or combined hemorrhage and shock, than any other known form of treatment." He even suggested that a transfusion prior to operation has prophylactic value, which procedure has recently been advocated in the presence of a moderate anemia or an anticipated blood loss during the operation.

Crile in "Hemorrhage and Transfusion" presented experimental evidence demonstrating the occurrence of hemoconcentration. As early as 1904 (*Am. J. Obst.* **2**:106, 1904) he stated "That is to say, the blood is transferred to the venous side. . . . The patient has been bled in his own vessels." This statement was based on his experiments on shock reported in 1899 (Surgical Shock, J. B. Lippincott Company), in which he reported the existence of an elevated venous pressure in traumatic shock. In this monograph he reported a decrease in "cardiac output," which was inferred chiefly from the pulse pressure record, and proposed his vasomotor exhaustion theory of the cause of shock. This concept was broadened in the book "Anoci-Association" into the "kinetic theory of shock." This hypothesis maintained that every adequate stimulus awakens associations, or "an ontogenetic or phylogenetic memory." These associations may be injurious, i. e. nociassociations, and it is the constant effort of the individual to reach a state of anociassociation. Noxious stimuli, traumatic or emotional, or noxious conditions, hemorrhage, infection, starvation, muscular exertion, cause "discharges of energy," which "when intense enough, produce extreme conditions called 'exhaustion' and 'shock.'" This theory was then applied to "the development of *the shockless operation through anociassociation.*" The patient was protected from emotional strain prior to and after the operation, the anesthetics were selected to exclude all stimuli from the brain, and the tissues were handled gently.

John Scudder in his book on shock (J. B. Lippincott Company, 1940) provides an excellent synopsis of the history of the signs and symptoms, the theories and the treatment of shock. A perusal of this book will reveal that all of the observations made in 1899 and 1909 by Dr. Crile had been made before; even blood transfusion for "shock" had been suggested by Heister as early as 1750 and had been used by John Hunter in 1776 and F. Jordan in 1881. But no one prior to Crile had investigated *the subject of shock so extensively. Further, Crile* placed blood transfusion on the therapeutic map, not only for shock and hemorrhage but for other conditions. However, it was the work of Landsteiner (1902) on blood groups and the development of the Kimpton-Brown tube method (1913), the syringe method (Unger 1915) and the sodium citrate method (Lewisohn, 1915) that rendered the use of blood transfusion widely applicable and utilizable in World War I. Crile made an outstanding contribution to the prevention of shock by teaching the importance of a proper preoperative and postoperative environment, of the selection of the appropriate anesthetics, and of gentleness in the manipulation of tissues.

His theory that shock is due predominantly to an exhaustion of the vasoconstrictor center has not withstood careful experimental analysis. The evidence indicates that this center remains reflexly active and perhaps hyperactive during the development of shock (Grodins, F. S., and Freeman, Smith: *Internat. Abstr. Surg.* **72**:1, in *Surg., Gynec. & Obst.*, January 1941). However, numerous investigators hold that either a decrease in vasoconstrictor tone or reflex arteriolar dilatation causes what is called primary shock or a moderate fall in blood pressure, from which recovery occurs spontaneously or which responds readily to treatment. The author of this answer holds with C. J. Wiggers (*Physiol. Rev.* **22**:111 [Jan.] 1942) that "extensive reflex arteriolar dilatation may occur as an incipient reaction during many catastrophes which lead to shock" and that "it should no longer be considered a sin to give thought to the possible role that the vasomotor center may play in determining the lethal character of peripheral circulatory failure." N. E. Freeman ("Burns, Shock, Etc.," Military Surgical Manuals, National Research Council, W. B. Saunders Company, 1943, vol. 5) says that "on the basis of clinical experience it is generally agreed that pain is a factor in the production of shock. Possibly the necessary use of anesthesia, in animal experimentation, so changes the physiologic reactions that shock cannot be produced by pain alone. . . . It seems likely, therefore, that the emotional state may play a significant part in the production of shock. Objective proof of this concept, however, is difficult to obtain."

Phemister (THE JOURNAL, April 28, 1945, p. 1109) properly emphasizes the view that a reduction in circulating blood volume is a more important factor in the genesis of shock due to tissue damage than nociassociations, according to existing evidence. His conclusion that blood and plasma transfusions irrefutably constitute the most effective treatment of shock confirms the statement made by Crile in 1909.

ELECTROMYOGRAMS OF TREMORS

To the Editor:—In THE JOURNAL Feb. 28, 1942, Dr. DeJong published the tracings of the tremor of paralysis agitans and of some fibrillations. Are there similar tracings of senile tremor, tremor of excitement or intention tremor also in the literature?

George H. Hoxie, M.D., Berkeley, Calif.

ANSWER.—No tracings of the specific tremors described in the query are available in the medical literature. Tremors of this type, however, have been recorded many times in laboratories, and electromyograms of the tremors in cerebellar diseases, athetosis and Sydenham's chorea have been published. New Work on the subject is about to be published in the *Archives of Neurology and Psychiatry.* This paper will give the electromyograms of patients suffering from neuroses precipitated by combat, and these will be contrasted with the tremors shown in Parkinson's disease, delirium tremens and the psychoneuroses of civilian life.

ALCOHOL AS A STERILIZING AGENT

To the Editor:—Please give me information concerning the efficacy of alcohol as a sterilizing agent. For example, when a tube of catgut has been opened and partly used, is it safe to put the remainder in a covered dish of alcohol and expect it to remain sterile? Again, for ordinary skin preparation and wiping prior to removing sutures or giving hypodermic injections, is the ordinary rubbing alcohol which contains some castor oil and some brucine as good as pure alcohol? Of course it is much cheaper for office and hospital use.

John H. Duncan, M.D., Sault Ste. Marie, Ont.

ANSWER.—Ethyl alcohol is an efficient disinfectant in certain concentrations. The most efficient strength is 70 per cent by weight (Price, P. B.: Ethyl Alcohol as a Germicide, *Arch. Surg.* **38**:528 [March] 1939). It is useful against contaminating organisms as well as the ordinary resident bacterial flora of skin (Price, P. B.: New Studies in Surgical Bacteriology and Surgical Technic, THE JOURNAL, Nov. 26, 1938, p. 1993). It is perhaps the best available agent for ordinary skin preparation and wiping prior to removing sutures or giving hypodermic injections. The solution should be properly prepared.

Alcohol is much less effective, however, in sterilizing catgut. It has been shown conclusively that alcohol will not sterilize raw catgut. One reason for failure is that the alcohol *does not*

come into contact with many organisms harbored in the cracks and folds of the strand. Another reason is that alcohol is ineffective against spores. Unquestionably a strand of heat sterilized catgut taken from a tube can be kept sterile in a covered dish of alcohol, but there is always a chance that the catgut may have been contaminated by handling or from the air, and there is no assurance that alcohol will completely counteract the contamination.

Many preparations of rubbing alcohol are in use. It is probably safe to say that most of them have relatively little skin disinfectant action. The concentration of alcohol in these preparations is usually too weak to be germicidal. After all, the primary purpose of "rubbing alcohol" is not to disinfect skin and it should not be expected to be a satisfactory substitute for germicidal preparations of alcohol. Brucine probably does not add anything to the disinfectant action of rubbing alcohol, and castor oil may actually lessen its germicidal effect. "Pure" alcohol is less effective than the 70 per cent, by weight, solution.

OLIGOSPERMIA AND STERILITY

To the Editor:—A white man aged 29 has oligospermia. He is in excellent health: his Hinton reaction is normal, as is his basal metabolic rate. He reported his last sperm count as 28 million per cubic centimeter; I did a recount and found 26 million. After a series of injections of antuitrin, the sperm count was found to be 12 million. Very much to my surprise, he told me that he had a 3 year old son who is in good health. When his wife did not become pregnant again after two years, both were checked and his condition was detected. Is it possible to have children with such a low sperm count, especially considering the fact that the motility of the sperm is very poor, and a high percentage of pathologic forms are present? If it is not possible to have a child with such a count, how can the change be explained since the patient has had no illness whatever since the last baby was born except an occasional cold?

M.D., Massachusetts.

ANSWER.—Moderate oligospermia is not inconsistent with fertility if the volume of the ejaculate is adequate and the motility and morphology of the spermatozoa are good. S. T. Meaker (*Human Sterility*, Baltimore, Williams & Wilkins Company, 1934) stated that pregnancy is improbable with sperm counts of less than 60 million, but he has since revised his opinion in favor of counts considerably lower. Poor motility inherent in the spermatozoa would be a serious fault; most cases of so-called necrospermia, however, are due to the fact that the specimen was not obtained and transported under ideal conditions. A high percentage of pathologic forms, on the other hand, present direct evidence of male infertility, all the stronger when the count is low.

The overall picture in this case is one of fertility so depressed that pregnancy, while not impossible, is definitely unlikely. It may well be that three years ago the semen was in all respects normal. Remarkable changes in male fertility, both for the better and for the worse, sometimes occur in a short space of months and without any reason immediately apparent. One must suppose that in cases of deterioration either the gonadotropic action of the anterior pituitary has diminished or the seminiferous tubules have become less responsive to stimulation. These phenomena may take place without obvious relation to the patient's general health.

A testicular biopsy would be informative. If this shows atrophy of the germinal epithelium, the outlook is unfavorable. In the absence of atrophy, attempts may be made to stimulate spermatogenesis. The first step should be a thorough survey of the patient's health and hygiene, with particular reference to such items as chronic focal infection, anemia, sex habits, diet, exercise and rest. Gonadotropic therapy is rational in theory though often disappointing in practice. The best results have been obtained from the combined use of pituitary and chorionic gonadotropins.

MEGAKARYOCYTES IN THROMBOPENIC PURPURA

To the Editor:—Are there any reliable methods for the determination of megakaryocytes in bone marrow? Are megakaryocytes increased in thrombopenic purpura? Can the response to splenectomy be predicted from the number of megakaryocytes?

Philip Pizzolato, M.D., New Orleans.

ANSWER.—The number of megakaryocytes can be counted in a certain standard area on a stained bone marrow film (Limarzi and Schleicher: THE JOURNAL, Jan. 6, 1940, p. 12) or the number can be determined in the counting chamber while making the usual total nucleated cell count. Both methods give only approximate values, as the quantitative estimation of any bone marrow cells by the puncture technic is open to considerable error. It usually suffices to know whether the megakaryocytes are increased, normal or decreased, and this information can be obtained from an examination of the bone marrow film under the low power objective. Each individual must familiarize himself with the normal number of megakaryocytes for the special technic employed. In thrombopenic purpura the megakaryocytes in the bone marrow are either normal or increased in numbers. It has not been established that the response of the platelets to splenectomy can always be predicted from the number of megakaryocytes. However, one should hesitate to remove the spleen of a patient in whom the megakaryocytes are definitely diminished or absent.

SUBCUTANEOUS AND INTRAMUSCULAR TEMPERATURE RESPONSE TO EXTERNAL STIMULATION

To the Editor:—Kindly furnish me with references concerning the penetrating effects of hot or cold baths on an extremity. In other words, what is the temperature at various depths beneath the skin after an extremity has been immersed in a bath of definite temperature for a definite time?

M.D., South Carolina.

ANSWER.—Determinations of the temperature changes produced within the living human extremities on exposure to hot and cold baths do not seem to have been made. However, such observations have been recorded for the temperature alterations from the application of the hot water bag and of the ice bag to the living human calf. Following the application of a hot water bag the skin surface temperature rose from 90 F. to a maximum of 110 F. within thirty minutes. The subcutaneous temperature rose from 91.2 F. to 105.5 F. in forty minutes and the intramuscular temperature (at a distance of about 2 inches beneath the skin surface) from 94.2 F. to 99.6 F. after fifty minutes. On the application of an ice bag the skin temperature fell to 43 F. in fifteen minutes, the subcutaneous temperature went to 70 F. in one hour and the intramuscular temperature to 79 F. after about two hours. While water is a more efficient agent for conductive heating or cooling, it appears reasonable to assume that the temperature changes described are of the same order as those taking place on the direct application of hot and cold water.

PENICILLIN AS PROPHYLAXIS TO POSTOPERATIVE INFECTION

To the Editor:—Would local and parenteral administration of penicillin be advisable as a prophylactic against infection and following cataract operation?

M.D., Louisiana.

ANSWER.—No. Penicillin is of value only in case the infection is due to an organism susceptible to the drug and then only when the blood and tissue concentrations of the drug are kept at a high level. It is obviously impossible to foretell what might be the infecting organism. Furthermore, intraocular infection following cataract extraction can be completely prevented by sterilization of the conjunctival sac before operation and by scrupulous asepsis during the operation.

WIRING IN FRACTURES OF THE JAW

To the Editor:—Who developed multiple loop wiring in fracture of the jaw? When was it first described?

Daniel Klein, Major, M. C., A. U. S.

ANSWER.—The principle of wiring the teeth in the upper and lower jaw as a means of fixation of fractures of the body of the mandible was first described by Thomas L. Gilmore in 1887. Multiple loop wiring, a modification of the Gilmore technic, was first described by R. T. Oliver in 1910 in an attempt to standardize the various methods employed.

IMMUNITY TO PNEUMONIA

To the Editor:—I should like to know whether recovery from an attack of pneumonia of a known type confers immunity against a subsequent attack of that same type of pneumonia.

Frederick G. Murray, M.D., Cedar Rapids, Iowa

ANSWER.—Demonstrable specific immunity does occur after an attack of pneumococcic lobar pneumonia, but it is of brief duration. Finland and Winkler (*Am. J. M. Sc.* 188:309 [Sept.] 1934) mention 4 instances in which two attacks caused by pneumonia of the same type occurred within a year. Recovery from an attack of pneumococcic pneumonia, therefore, may not confer immunity against a subsequent attack.

THE RELATION OF EFFORT TO ATTACKS OF ACUTE MYOCARDIAL INFARCTION

LIEUTENANT COLONEL HERRMAN L BLUMGART

Associate Professor of Medicine, Harvard Medical School (on leave of absence); Visiting Physician, Beth Israel Hospital (on leave of absence)

MEDICAL CORPS, ARMY OF THE UNITED STATES

In army experience the occurrence of acute myocardial infarction during or soon after strenuous effort is striking. The relation between effort and attacks of coronary occlusion or myocardial infarction has been the subject of considerable discussion because of the important clinical and other practical implications.[1] Thus, Master and his associates [2] analyzed the events preceding 530 attacks of coronary thrombosis and found that only 2 per cent followed unusual exertion, 5 per cent followed excitement and 37 per cent occurred during mild activity. They pointed out that, since half of the day of normal persons is spent in mild or moderate activity, one might well expect half of all attacks to occur during this period and concluded that effort is not a precipitating factor in causing myocardial infarction. These authors state that "although both angina pectoris and coronary artery thrombosis have the same underlying pathologic condition, namely coronary sclerosis, they differ entirely in respect to the exciting cause of the attack." Boas [3] as well as others [4] has challenged this point of view, stating that in his experience bodily effort directly may induce closure of a coronary artery with cardiac infarction or may initiate the syndrome of angina pectoris. Boas [5] states:

I fully agree with Master that coronary thrombosis very often occurs while the individual is at rest or asleep and that in many cases no antecedent injury or effort has taken place. But to argue from this that such accidents are not competent causes of coronary thrombosis appears incorrect. The fact that pneumothorax is due usually to pulmonary tuberculosis or to the rupture of an emphysematous bleb does not negate the fact that it may follow trauma to the chest; or that cerebral hemorrhage is caused usually by disease of the cerebral arteries that it may not be due to trauma to the head

As Bean pointed out, the fact that most motor accidents do not occur at speeds of 70 miles an hour does not prove that such speed may not be concerned in some motor accidents.

Most military personnel are called on to undertake strenuous effort and, particularly in the instance of some officers from civilian life, such effort is often decidedly unaccustomed. It therefore might be anticipated that if effort and myocardial infarction were causally related an increased number of such cases might be witnessed in the Army. This is indeed the case. The medical officers at practically every one of the many hospital installations which I have visited have witnessed one or more such instances. In each case unequivocal electrocardiographic tracings of myocardial infarction were observed during life and/or an acute fresh occlusion of one of the three major coronary arteries was disclosed at postmortem examination. In the 8 cases in which electrocardiographic tracings were made, the changes were characteristic. In the 3 patients who died before such tracings could be made, fresh thrombosis of a coronary artery was observed in 2 and fresh subintimal hemorrhage in the other case post mortem. The following 11 cases were selected from a larger available series because of the adequate available data and because they illustrate the varying relation between effort and acute myocardial infarction:

CASE 1.—A major in the Field Artillery, aged 35, had had "gas" with epigastric and substernal distress for about eighteen months, precipitated by nervousness or anxiety, relieved by "belching" and occasionally by vomiting, but not related to exertion, eating or change in weather. On the afternoon before the day of admission he played baseball and hit a home run. As he reached the home plate "suddenly everything went black." He collapsed to the ground. He recovered sufficiently after five or ten minutes to get up and after half an hour walked to his quarters. At midnight he suffered severe substernal distress, dyspnea and cough. When admitted to the hospital at 3:30 a. m. he showed labored respiration, cyanosis and heart sounds of poor quality. The blood pressure was 95/78. The white blood cell count was 16,400. X-ray examination of the chest revealed evidence of pulmonary engorgement; there was no evidence of a pulmonary infarct. Electrocardiographic tracings were characteristic of cardiac anterior wall infarction. The patient rallied somewhat during the day under therapy including oxygen, but then pulmonary edema and dyspnea increased, the pulse became weak and the patient died eighteen hours after the ball game.

On postmortem examination of the heart, scattered foci of fibrosis were seen throughout the apex, and one area of old scar tissue measuring 2 cm. in diameter was evident in the left anterior ventricular wall. Above the latter area, acute necrotizing myomalacia was revealed grossly and microscopically. The left anterior coronary artery showed advanced arteriosclerosis with narrowing and one old healed occlusion. About 4 cm from the origin of this artery, a fresh antemortem thrombus was found.

CASE 2.—A private aged 30 played volley ball immediately after calisthenics and developed substernal oppression and

unusual dyspnea. He experienced persistent weakness for two days following this episode and then developed acute dyspnea, orthopnea and chest pain. *Physical examination on admission* disclosed orthopnea, dyspnea, ashen gray cyanosis, cold sweat, heart rate 100 per minute, weak cardiac sounds, gallop rhythm and a blood pressure of 124/80. The patient gradually improved during the following four days but showed evidence of pulmonary edema. Serial electrocardiographic tracings revealed progressive changes characteristic of anterior wall infarction. He gradually improved and was discharged from the hospital twelve weeks later.

CASE 3.—A private aged 37 experienced occasional vague substernal discomfort, unrelated to exertion, during ten days before admission. On the day before admission he ran a distance of 1 mile, immediately following which he experienced persistent weakness, which continued until he fell asleep. At 2 a. m. he was awakened by severe substernal pains, with numbness radiating to the left arm; he felt prostrated and had drenching cold sweat. He was admitted immediately to the hospital. Physical examination revealed evidence of shock with rales at both bases. The heart rate was 120 per minute. During the next three days the substernal oppression gradually subsided and the patient made an uneventful recovery. Serial electrocardiographic tracings showed pronounced changes characteristic of anterior wall infarction.

CASE 4.—A captain in the Signal Corps, aged 41, collapsed while on a hike and was dead on arrival at the hospital. Examination of the heart showed advanced arteriosclerosis of the left coronary artery and a fresh complete occlusion of the right coronary artery caused by friable atheromatous material.

CASE 5.—A first lieutenant in the Motorized Division, aged 26, while engaged on maneuvers during the night complained that he was dizzy and felt sick. He was taken to a nearby house, became acutely dyspneic and died within a few minutes. Examination of the heart revealed a fresh thrombus in one of several anomalous subdivisions of the right coronary artery. Old fibrotic changes were evident on the posterior wall of the left ventricle near the base.

CASE 6.—A captain in the Transportation Corps, aged 34, had felt perfectly well and was running an obstacle course, toward the end of which he had to scale a 12 foot wall. He felt perfectly well when he came to this obstacle. He failed to swing over it on the first attempt. On the second attempt he suddenly developed sharp chest pain, felt exhausted, had to gasp for breath, and broke out in profuse perspiration. The pain was initially substernal but soon radiated over the entire anterior chest and to the shoulders and arms. The substernal pain, very severe, subsided considerably during fifteen minutes and he finished the course without scaling the wall. At the end of about two and one-half hours the substernal distress disappeared entirely. Thereafter he repeatedly noted shortness of breath and mild substernal pain on exertion, disappearing in about five minutes on rest. He did not seek medical advice. These symptoms persisted and he had one severe attack following strenuous effort and was finally hospitalized. Physical examination showed a normal sized heart. The blood pressure was 106/84. Electrocardiographic tracings showed the characteristics in the first and fourth leads of a previous anterior wall infarction.

CASE 7.—An infantry colonel aged 56 had been assigned to sedentary duties for a period of two years and was then transferred to an infantry division for training and shipment overseas. To qualify for overseas duties he was required to complete the run of an obstacle course in a given period of time. Immediately after completion of the qualifying run, while taking a shower, he was seized with severe substernal pain and choking sensations and collapsed. He was immediately taken to the hospital. The findings on physical examination and the electrocardiographic tracings were characteristic of acute myocardial infarction. He made an uneventful recovery and was retired because of arteriosclerotic heart disease.

CASE 8.—A captain aged 47 was seized with precordial discomfort immediately after exercise in the gymnasium. He was advised to see a medical officer but did not do so despite the fact that he continued to have considerable precordial discomfort during the night. He sought medical advice the following afternoon. The electrocardiographic tracings were equivocal, and he was asked to exercise jumping on one foot while another electrocardiographic tracing was taken. Directly following this he collapsed and went into severe shock. He was then first seen by one of the officers in the medical service, who made a diagnosis of coronary thrombosis. The heart rate was slow, gallop rhythm was evident and the blood pressure was 100/60. His condition was critical, but under appropriate therapy he improved and eventually recovered. Serial electrocardiographic tracings were characteristic of posterior wall infarction.

CASE 9.—A staff sergeant in the Coast Artillery, aged 56, died suddenly during a tactical march with his unit. Postmortem examination revealed arteriosclerosis of all three coronary arteries. In the wall of the left anterior descending artery "areas of fresh hemorrhagic extravasation and mixed round cell infiltration" were observed.

CASE 10.—A first lieutenant in the military police, aged 44, returned from a 20 to 25 mile march, felt well, ate dinner and one hour later suddenly experienced substernal oppression. He collapsed, was unconscious for several hours and was transported to the hospital. He then experienced severe precordial pain, choking sensations and dyspnea. He gradually improved and was retired from the service. Serial electrocardiographic tracings were characteristic of posterior wall infarction.

CASE 11.—A private aged 31 had been a clerk in civilian life and after induction was assigned to similar duties in a finance department at a port of embarkation. He was then transferred for basic training. As part of the program of basic training he engaged in vigorous swimming in very cold water with his platoon for one and one-half hours. He got out of the water at 11:15 a. m. and while marching back to his barracks at 11:25 was suddenly seized with extremely severe viselike retrosternal pain, which, to quote his words, was "almost more than I could stand. I do not know how I made it back." He nevertheless marched the three fourths of a mile to his barracks, went to bed and was pale, drenched in cold sweat and dyspneic. The severe pain, after persisting one and one-half hours, subsided somewhat and he was admitted to the hospital. Physical examination revealed impending shock. But he rallied under appropriate therapy. The substernal distress disappeared after four days. Serial electrocardiographic tracings were characteristic of posterior wall infarction.

COMMENT

The question of the relation of effort to acute myocardial infarction is of considerable practical as well as theoretical importance. Legal decisions in civilian life and the line of duty determination in military service are often vitally affected. In case 7, for instance, although the officer had been in service for two years, it was initially decided that effort bore no relation to the attack of acute myocardial infarction and the line of duty determination was "no." Recognition of the relation of effort to acute myocardial infarction may be of great importance in diagnosis as well as in proper clinical management. Thus, failure to recognize the interrelation between effort and acute myocardial infarction in case 8 resulted in the continuation of exercise by the patient and even a request by a medical officer to undertake the effort of an exercise tolerance test.

The clinical experience illustrated by the foregoing cases emphasizes certain hitherto established facts which are not sufficiently kept in mind. The quality of cardiac pain is mimicked with fidelity by disease of other organs, and therefore a diagnosis of noncardiac disease is often mistakenly made. Clinical experience in the Army, as well as in civilian life, is in accord with that

of French and Dock,[6] who state that less than half of those who mentioned prodromal symptoms sought professional advice and that only 1 of the 14 cases with symptoms which suggested this condition had received a correct diagnosis and been treated before the fatal attack. In their communication, which has appeared since the present study was undertaken, they analyzed the findings in 80 fatal cases in which death seemed due to uncomplicated coronary lesions. They state that:

> Marching with a pack is considered as "vigorous exercise" and it is remarkable, in view of the soldier's chances for vigorous activity on or off duty, that about 40 per cent of these men had not had such exercise within a day or so of their final cardiac break.
>
> In 15 cases sudden death or the onset of severe pain in a fatal seizure occurred during vigorous or violent muscular effort. Twenty-six patients, or 35 per cent, had the fatal attack within one to several hours after "vigorous exercise."

Arteriosclerosis was the underlying pathologic basis of coronary occlusion in all cases.

Cardiac pain, particularly that of angina pectoris, is characterized by appearing during effort or emotional stress and by relief on rest. Appreciation of the importance of effort or excitement as a precipitating factor in angina pectoris or acute myocardial infarction should lead the physician to make direct inquiry regarding all attendant circumstances prior to the onset of the attack. Much significant information not spontaneously volunteered by the patient frequently will be uncovered. The appearance of distress on exertion or under emotional stress should indicate a tentative diagnosis of angina pectoris, of coronary failure or insufficiency, or of myocardial infarction[7] until such a diagnosis is clearly excluded on the basis of further evidence. In such a situation vigilance must be exercised for the signs or symptoms of myocardial infarction. In some instances, such as case 3, persistent weakness may be the sole finding, the significance of which may be corroborated only subsequently by progressive characteristic changes in later electrocardiographic tracings.

It is of interest that, aside from emotional stress and effort, other concomitant factors, such as exposure to cold or eating, which increase the work of the heart may superimpose their effect. Thus, in cases 7 and 11 exposure to cold by swimming and a cold shower may not have been entirely coincidental.

In the light of these considerations, medical officers should maintain close supervision over all those assigned to their care when they undertake strenuous or prolonged activities. The occurrence of substernal distress under these circumstances should cause the medical officer to advise cessation of such strenuous activity in order to forestall, when possible, the development of acute myocardial infarction. Even if myocardial infarction occurs, immediate enforcement of complete rest may be expected to influence the extent of the infarct and favor recovery. In any patient, previously well, who suddenly develops angina pectoris on rest or on exertion, one must suspect coronary narrowing or occlusion even if none of the signs of cardiac infarction appear.[7]

The several mechanisms which are operative in producing myocardial infarction are clarified by recent advances in our knowledge of the pathology of coronary arteriosclerosis and may be summarized as follows:

1. *Relative Ischemia.*—In previous studies that my associates and I have made on patients dying with acute myocardial infarction, no fresh thrombosis or occlusion was found by the injection plus dissection method of Schlesinger[8] in certain instances. It is logical to assume on the basis of actual pathologic findings and clinical experience that an artery narrowed by arteriosclerotic changes may transmit sufficient blood for the ordinary needs of the myocardium but may not be competent to transmit the increased blood flow required by the heart during effort. The heart muscle, under such circumstances, suffers from relative ischemia. If this is sufficiently prolonged, irreversible damage, i. e. infarction, results[9] (case 3). Sudden death may be due to the development of ventricular fibrillation or cardiac standstill because of myocardial ischemia in the absence of any fresh pathologic changes in the coronary arteries.

2. *Subintimal Hemorrhage.*—That coronary occlusion and coronary thrombosis frequently result from hemorrhages within the coronary arterial wall has been clearly demonstrated.[10] These pathologic studies offer an adequate basis for the sudden onset of symptoms of angina pectoris or of coronary occlusion. The formation of a hematoma within the wall of an artery may raise the intima and partially occlude the lumen. This early lesion was revealed in case 9, in which death occurred before there could be any further sequence of events. At times the hemorrhage may elevate the intima sufficiently to bring opposing surfaces together and completely occlude the lumen. In some instances the hemorrhage may rupture the intima, exposing a raw open hemorrhagic wound. This raw surface constitutes a favorable site for the development of a thrombus. Subintimal hemorrhage and subsequent thrombus formation may develop gradually over a period of many days or even a week or two and serve to explain some cases in which an appreciable interval separates the strenuous activity from the acute attack. It is not believed that subintimal hemorrhages occur in a normal artery but take place only in an atheromatous lesion.

The exact factors which determine hemorrhage from an intimal or subintimal capillary into the wall of an arteriosclerotic coronary artery have been the subject of speculation by various authors.[11] It has been suggested that intimal capillaries, since they arise directly from the lumen, are particularly susceptible to the transient increased coronary pressure induced by exertion or emotion. Intimal or subintimal capillaries are more liable to rupture if softening, which is a physical characteristic of atheromatous lesions, occurs and allows the pressure of blood within the capillary to dilate its walls to the extent that rupture is more prone to occur. The fragility of the capillary wall may also be affected

by anoxemia, by the presence of local or general toxic factors and by impaired nutrition. In addition, one may speculate as to whether the capillary wall may not share with neighboring tissues the anoxemia due to relative insufficiency of blood flow during effort or emotion and thus be more liable to rupture.

3. *Rupture of Atheromatous Abscess.*—Attacks of acute myocardial infarction following effort may also arise as the result of coronary occlusion following the rupture of an atheromatous abscess,[12] as in case 4.

Recognition of the causal relationship of effort to acute myocardial infarction should not lead the medical officer or physician to ascribe every attack of acute myocardial infarction to preceding effort. The occurrence of acute myocardial infarction in the foregoing cases during or immediately after strenuous effort clearly establishes a causal relationship. As with most diagnostic problems in medicine, the relation of effort to an attack of myocardial infarction in a particular patient may be certain, may be probable, suggestive or improbable or may be considered to be nonexistent. The relation is considered definite if the following criteria are satisfied.

1. The development and increase of cardiac symptoms such as pain or substernal distress during or immediately following unusual effort (cases 1-9, 11).
2. Continuation of the symptoms after cessation of effort.
3. The presence of the clinical signs and symptoms of acute myocardial infarction.
4. Development of the characteristic electrocardiographic pattern of acute anterior, posterior or lateral wall myocardial infarction.

If several days intervene between effort and development of acute myocardial infarction, the relation cannot be considered definite unless there is a continuity of symptoms bridging the interval.

The pathologic mechanisms that have been described offer a rational basis for those cases in which no symptoms are experienced for several days or a week or more following unusual effort. The sequence of pathologic events revealed by postmortem studies indicates that subintimal hemorrhages may lead to a gradual growth of the hematoma within the arterial wall or to the gradual formation of an intra-arterial thrombus over the site of the subintimal hemorrhage. Under such circumstances or when the thrombus propagates slowly, particularly when some prior collateral circulation has been developed, a symptomless interval of considerable duration between effort and myocardial infarction is understandable. The occurrence of such a succession of events in a patient with a symptomless interval should, however, be accepted with great caution and is to be considered probable, suggestive or improbable according to the nature of the effort, the length of the symptomless interval and the presence or absence of the other criteria mentioned.

In a patient in whom postmortem examination discloses arteriosclerotic obstruction or narrowing of the coronary artery but no fresh changes, the possibility of relative ischemia causing cardiac standstill or ventricular fibrillation must be entertained.

The evidence brought forward in this communication and by others demonstrates the importance of effort in precipitating attacks of acute myocardial infarction in a small but definite proportion of cases and supports the ischemic theory of cardiac pain. That emotion may likewise be the responsible precipitating factor is generally recognized and is further supported by objective evidence for the existence of reflex factors.[13] If inordinate myocardial strain is avoided in those suffering from angina pectoris, and if, in those suffering from acute myocardial infarction, the diagnosis is made early and appropriate treatment is instituted promptly, many catastrophes doubtless can be avoided. Clinical evidence, experimental observations and our knowledge of the collateral circulation within the heart conform to these considerations.[14]

12. Leary, T.: Pathology of Coronary Sclerosis, Am. Heart J. **10**: 328, 1935.

SUMMARY AND CONCLUSIONS

1. The histories of 11 patients with acute myocardial infarction consequent to strenuous effort illustrate the relationship between the two.

2. The clinical criteria which must be satisfied to demonstrate this relationship are (*a*) the development and increase of cardiac symptoms such as pain or substernal distress during or immediately following unusual effort, (*b*) continuation of the symptoms after cessation of effort, (*c*) presence of clinical signs and symptoms of acute myocardial infarction and (*d*) the development of characteristic electrocardiographic pattern of acute anterior, posterior or lateral wall myocardial infarction.

3. The pathologic mechanisms which induce acute myocardial infarction during or soon after effort are (*a*) subintimal hemorrhages or the rupture of an atheromatous abscess following strenuous effort and (*b*) the occurrence of relative ischemia brought about by strenuous effort and resulting in a need for increased blood flow which the arteriosclerotic vessels are unable to meet.

PENICILLIN IN THE TREATMENT OF PNEUMOCOCCIC MENINGITIS

A STUDY OF 67 CONSECUTIVE CASES

EMANUEL APPELBAUM, M.D.
AND
JACK NELSON, M.D.
NEW YORK

During a period of nearly thirty-five years the members of the Division of Acute Infections of the Central Nervous System of the New York City Health Department have been studying the effect of the various forms of therapy in bacterial meningitis. Before the newer chemicals became available the case fatality in pneumococcic meningitis was 100 per cent.

The use of azosulfamide and sulfanilamide slightly improved the prognosis. The advent of the more potent sulfonamides marked a further advance in the treatment of this disease. In an unpublished series of 139 cases of pneumococcic meningitis treated with sulfapyridine, sulfadiazine, sulfathiazole or a combination of these (and specific serum when available) we obtained 49 recoveries. The recent introduction of penicillin led us to try the use of this drug in pneumococcic meningitis.

From the Bureau of Laboratories, New York City Health Department.
The penicillin used in these studies was furnished by the Office of Scientific Research and Development from supplies assigned by the Committee on Medical Research for experimental investigations recommended by the Committee on Chemotherapeutics and Other Agents of the National Research Council.

MATERIAL

This report is based on a series of 67 consecutive cases seen between Oct. 10, 1943 and May 1, 1944. The diagnosis was definitely established in each instance by culturing and typing the organisms from the spinal fluid.

TABLE 1.—*Age Distribution in 67 Cases of Pneumococcic Meningitis*

Age Years	Number of Cases	Number of Recoveries
	Number of Recoveries in Each Group	
Under 1	11	4
1 to 10	6	5
11 to 20	2	1
21 to 30	1	1
31 to 40	7	4
41 to 50	12	3
51 to 60	14	5
61 to 70	10	1
71 to 80	4	2
Totals	67	26

CLINICAL ASPECTS

Table 1 shows the age distribution of the patients in this series. The wide range in age is quite evident. It is also of interest to note that the number of patients under 1 year together with those above 50 years of age constitute more than half of the total number of cases. Most of the patients presented the typical picture of meningitis on admission. The individual patients showed considerable variation in the severity of the disease, but most of them appeared critically ill and 12 even moribund.

Consideration of the foci of infection is of the utmost importance. As shown in table 2, a definite focus in the ear or mastoid or both was found in 30 of these 67 cases. In 1 of the cases with otitis and mastoiditis there was also a petrositis. While this series shows a record of only 2 instances of definite sinus involvement, it is possible that this condition existed more frequently than it was recognized. In 1 instance there was a fractured skull and in 1 a head injury with a possible fracture. In 17 patients the presence of pneumonia was regarded as the probable primary focus. In 2 of these there was a complicating empyema and in 1 instance a vegetative endocarditis. There remained 16 cases in which the meningitis was preceded either by no obvious illness or by a simple upper respiratory infection. It is highly probable also that in not a few of the cases there were multiple foci of infection.

TABLE 2.—*Primary Foci of Infection*

Type of Focus	Number of Cases	Number Recovered
	Number of Recoveries in Each Group	
No known focus*	16	4
Otitis media with or without mastoiditis	30	15
Pneumonia	17	5
Sinusitis	2	0
Head injury	2	2
Total	67	26

* In this group were also included cases of simple respiratory infections.

BACTERIOLOGIC DIAGNOSIS

Diagnostic lumbar punctures were performed in all of the cases on admission. The cerebrospinal fluid showed varying degrees of turbidity. The cells were greatly increased in number with polymorphonuclears predominating. In the majority of instances the protein content was moderately to greatly increased. Sugar was either absent or considerably diminished in almost all instances. The diagnosis was confirmed bacteriologically in all cases. Stained smears of the cerebrospinal fluid showed varying numbers of gram positive diplococci in 63 instances. Pneumococci were grown from the fluid in all of the 67 cases. The organisms were typed in all the cases from the cultures and in many instances directly from the spinal fluid. The distribution of these types is shown in table 3. It may be of interest to note that when type III was recovered the meningitis was almost always secondary to otitis media, mastoiditis or sinusitis. Blood cultures were made in 49 of the cases prior to the institution of sulfonamide or penicillin therapy. These were positive in 33 instances.

TREATMENT

All the patients in this series were treated with penicillin. In all but 1 instance sulfonamides were used prior to the institution of penicillin therapy. Sulfathiazole alone was used in 1 case. In the remaining 65 cases sulfadiazine was employed either alone or combined with sulfathiazole. The total amount of sulfonamide given before penicillin was begun varied from 1.5 to 97 Gm., with an average of 22 Gm. The organisms isolated from the spinal fluid in every case were tested for sulfonamide sensitivity. In only 1 of these was there evidence of sulfonamide fastness. In 4 instances there was already evidence of a satisfactory clinical response to sulfonamide as well as a sterile spinal fluid at the time penicillin therapy was instituted.

5	5	13	0
6	4	14	1
7	3	21	1
8	2	Unknown	8
Total			67 cases

The duration of illness before treatment with penicillin varied from one to twenty-one days. As shown in table 4, 41 of the 67 patients were treated within the first four days of illness.

Rammelkamp and Keefer [1] have demonstrated that penicillin administered intravenously or intramuscularly does not pass through the meningovascular barrier in significant quantities. Injected intrathecally,[2]

1. Rammelkamp, C. H., and Keefer, C. S.: The Absorption, Excretion and Distribution of Penicillin, J. Clin. Investigation **22**: 425 (May) 1943.

2. Rammelkamp, C. H., and Keefer, C. S.: The Absorption, Excretion and Toxicity of Penicillin Administered by Intrathecal Injection, Am. J. M. Sc. **205**: 342 (March) 1943.

penicillin is slowly absorbed from the subarachnoid space and may be detected in the spinal fluid thirty-one and one-half hours later. In subjects with meningitis absorption of penicillin after intrathecal injection was more rapid than in normals, but significant amounts of the antibiotic agent remained in the spinal fluid for a period of twenty-four hours. It was also demonstrated that lumbar injections resulted in a diffusion of the penicillin throughout the ventriculo-subarachnoid space. In the treatment of meningitis therefore it seemed necessary to use penicillin intrathecally as well as intravenously or intramuscularly.

All the patients in this series received penicillin intraspinally following the removal of an equal or somewhat larger amount of spinal fluid. Sodium penicillin was dissolved in isotonic solution of sodium chloride in a dilution of 1,000 units per cubic centimeter. The intrathecal dosage varied from 5,000 to 20,000 units and was administered at twelve or twenty-four hour intervals. In a few instances the drug was also administered intracisternally or intraventricularly and, in 2 cases, subdurally. The intrathecal administration of penicillin was as a rule continued for a varying number of days after clinical improvement was manifest and the spinal fluid no longer showed organisms or diminution in the sugar content. This precaution was necessary because of the frequency of relapses in this form of meningitis. The total intraspinal dosage varied from 10,000 to 700,000 units, with an average of 175,000 units. It may be noted that in 3 instances the intraspinal route of administration alone was used.

TABLE 5.—*Initial Response to Penicillin and Ultimate Outcome of Case*

Type of Response	Number of Cases	Recovery	Death
Good	28	21	7
Fair	11	5	6
None	28	0	28
Total	67	26	41

Penicillin was also administered intramuscularly in most of the cases and in 11 instances it was administered intravenously by the continuous drip method. There were only 2 patients who did not receive penicillin either intramuscularly or intravenously. For the intramuscular administration the drug was prepared in a dilution of 5,000 units per cubic centimeter of saline solution and administered in doses of 2,500 to 10,000 units every three to four hours. When the drug was used intravenously we employed the continuous slow drip method at the rate of 2,500 to 5,000 units per hour. The total amount of penicillin administered intramuscularly or intravenously varied from 20,000 to 1,840,000 units, with an average of 400,000 units. It may be of interest to note that in 2 instances following mastoidectomy the operative wound was irrigated from three to four times a day with a solution of penicillin in a dilution of 1 to 1,000 units per cubic centimeter. This was repeated for four and nine days respectively.

In all but 13 instances sulfonamides were discontinued at the time penicillin therapy was instituted. Four patients received also antipneumococcus serum intravenously or intramuscularly or by both routes. A mastoidectomy, unilateral or bilateral, was performed in 14 instances. Other nonspecific measures of therapy included the use of insulin for 2 diabetic patients and the not infrequent administration of transfusions in many instances.

RESULTS

In this series of 67 cases there were 26 recoveries and 41 deaths, a recovery rate of 39 per cent. It will be seen from table 1 that the mortality was higher in the extremes of life, which include infants under 1 year and adults over 50 years of age. There also appeared to be a relationship between the primary focus of infection and the mortality, as shown in table 2. Perhaps the most definite correlation existed between bacteremia and the outcome. Among 33 patients with a positive initial blood culture there were 10 recoveries, while among 16 patients with negative blood cultures there were also 10 recoveries. On the other hand there was no evidence of a correlation between the duration of illness prior to the institution of penicillin therapy and the penicillin therapy and the outcome.

As shown in table 5, an initial favorable response was noted in 28 instances. In 21 of these, improvement progressed satisfactorily terminating in recovery, and in 7 cases the improvement was only temporary, resulting finally in a fatal issue. There were 28 patients who at no time showed any evidence of a clinical response and who died. It should be noted that among those who died there were 8 patients who were treated for less than twenty-four hours and received a total of less than 80,000 units of penicillin. The fatal group included also 1 instance of severe congestive heart failure, 2 cases of diabetes mellitus and 1 instance of severe sulfonamide intoxication. It is probable that these associated conditions were factors contributory to death. In 2 instances the development of brain abscess either early or late in the course of the disease undoubtedly contributed to the death of the patients. There was 1 patient with meningitis, pneumonia and endocarditis who at the time of her death showed no evidence of meningeal involvement. This was confirmed by the necropsy findings.

As previously noted, sulfadiazine was continued in the treatment of 13 of the patients after penicillin was instituted. Of these, 5 recovered and 8 died.

SPINAL FLUID CHANGES DURING THE COURSE OF TREATMENT

We have already referred to 4 instances in which the spinal fluids were sterile at the time of institution of penicillin therapy. In the remaining 65 cases, organisms were found in the spinal fluid prior to the use of this drug. With the institution of penicillin therapy fairly prompt disappearance of the pneumococci was noted in a vast majority of the cases. For example, the spinal fluid culture became sterile within forty-eight hours in 53 cases, and a negative smear was obtained within seventy-two hours in 36 instances. However, it should be emphasized that the early disappearance of the organisms could not be relied on as an index of the control of the infection.

With regard to the spinal fluid sugar, a return of this substance to normal within five days was observed in 31 patients. It is important to note that 20 of these recovered. It would seem therefore that an early return of the sugar to normal may be regarded as a favorable prognostic factor. It is necessary to caution against misinterpreting as normal the rise in the spinal fluid sugar resulting from intravenous glucose infusions.

In this connection it may be noted that penicillinase was not used in the cultures of this series. The effect of this enzyme on spinal fluid cultures is at present under investigation in our laboratory.

Penicillin determinations were made on each specimen of spinal fluid withdrawn. In 48 instances the spinal fluid organisms were studied for sensitivity to penicillin. These details will not be discussed at present but will form the subject of another report.

As mentioned previously, positive blood cultures were obtained in 33 cases before the initial sulfonamide therapy. Following penicillin therapy a blood culture was available in only 15 of these patients, in 13 of whom it became sterile.

It is well known that pneumococcic meningitis at times shows a tendency to relapse. In our series there were 7 instances with one or more relapses. In these cases there was evidence, both clinical and laboratory, of control of the infection for periods varying from three to thirty days before the disease recurred. Four of the patients with relapses recovered and 3 died.

COMPLICATIONS

In 2 instances the meningitis was complicated by brain abscess. These terminated fatally. The presence of subarachnoid block was noted in 6 cases. It is possible that the intrathecal penicillin therapy contributed toward the development of the complication. In 1 instance a meningeal infection due to Bacillus prodigiosus was superimposed in the terminal phase of the patient's illness.

REACTIONS

In 3 instances there were local tissue reactions at the site of the penicillin injection. These cleared up fairly rapidly. There were no other untoward effects following penicillin therapy in this series of 67 cases.

COMMENT

It is clear from this study that the introduction of penicillin has as yet not solved the problem of the treatment of pneumococcic meningitis. While this antibiotic agent was highly effective in the treatment of an appreciable number of cases, it proved ineffective in the majority of instances. However, there is no doubt that the use of penicillin resulted in the recovery of some patients who had failed to respond to sulfonamide.

Several factors contribute to the difficulty in successfully treating pneumococcic meningitis. The most important of these in our opinion is the fact that the meningitis is usually secondary to one or more primary foci of infection, many of which cannot be completely eradicated. We are at variance with a recent report,[3] based on a small series of cases, which minimizes the importance of the removal of suppurative foci. In our experience the complete eradication of the primary foci of infection is of the utmost importance in the management of this form of meningitis. Of course, a patient may recover without an operation. On the other hand, we have had 7 cases in which a mastoidectomy resulted in striking improvement after there had been failure to respond to penicillin therapy. In this connection we wish to stress that not infrequently a severe mastoiditis may fail to present clinical symptoms and occasionally even radiographic evidence of involvement.

3. Waring, A. J., Jr., and Smith, M. H. D.: Combined Penicillin and Sulfonamide Therapy in the Treatment of Pneumococcic Meningitis, J. A. M. A. 126:418 (Oct. 14) 1944.

Among other factors which militate against the success of therapy is the frequent presence of bacteremia. For instance, in this series of 33 patients with positive blood cultures 23 died, and among 16 cases with negative blood cultures there were only 6 deaths. Sometimes the infection is so overwhelming that the patient succumbs before adequate therapy can be administered. Furthermore, there is much that is unknown in regard to the bacteriology of the organisms, particularly with respect to the virulence of the various strains.

The precise method of treatment must at present be regarded as tentative. A number of important problems in connection with the employment of penicillin still remain to be investigated. These include an evaluation of the use of massive doses of the drug and the treatment of the disease with a combination of penicillin and sulfonamide.

SUMMARY

1. Sixty-seven consecutive patients with pneumococcic meningitis were treated with penicillin intrathecally and also intravenously or intramuscularly. In all but 1 instance, sulfonamides were used prior to the institution of penicillin therapy.

2. Of these 67 patients, 26 recovered and 41 died, representing a recovery rate of 39 per cent.

3. Thirteen of the patients were treated with a combination of penicillin and sulfadiazine. Of these, 5 recovered and 8 died.

4. The factors contributing to the difficulty of successfully treating pneumococcic meningitis include the presence of primary foci of infection, which are frequently inaccessible, the presence of bacteremia in many instances, and the occasional appearance of the disease in a fulminating form.

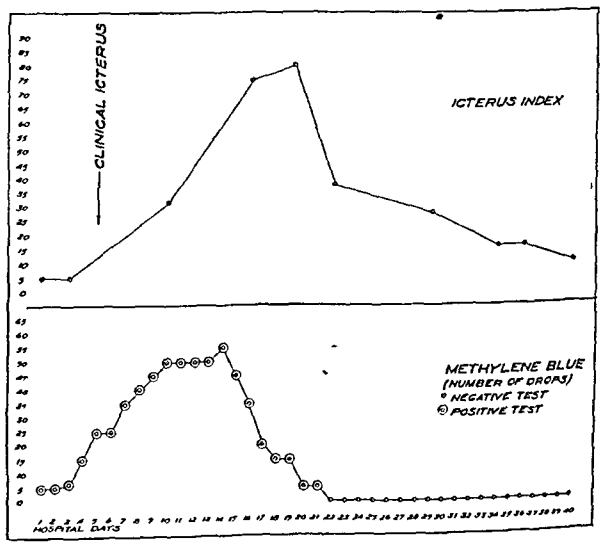
5. While penicillin was highly effective in the treatment of an appreciable number of cases, it proved ineffective in the majority of instances. It is evident that further investigation is needed to solve the problem of the treatment of pneumococcic meningitis.

Blaise Pascal (1623-1662).—The "great moralist," Blaise Pascal, was also a great scientist. His "Thoughts" ("Pensées") and "Letters"—in which he said "Pardon the length of this letter; I have not time to write you a short one"—are gems of French literature. Yet the sincere Jansenist turned to the dice game and the trials of the gaming table to develop, after Cardan, an unscrupulous Italian mathematician, and with Fermat, a cryptic French attorney, the mathematical theory of probability on which much of modern scientific thinking rests. Current weather forecasting and present day meteorology, on which the fortunes of aerial warfare depend, could hardly have been born until some one had established what Pascal—with the help of his brother-in-law, F. Perier—proved in the "Great Experiment" on the Puy de Dome; namely, the weight of the mass of the air. Here quoted is "the story of the great experiment," published posthumously in 1663. Employing Torricelli's recently invented barometer, Pascal slew forever the myth that "nature abhors a vacuum." Pascal was a child prodigy; before he was 11 he had taught himself geometry, drawing figures with charcoal on the tiles of his playroom and giving his own names to the lines and curves which his doting father had forbidden him to study. A great mathematician, inventor of the adding (calculating) machine and the hydraulic press, Pascal has been honored by having a law (of fluid pressure), a triangle and a mystic hexagram named after him.—The Autobiography of Science, edited by Forest Ray Moulton and Justus J. Schifferes, New York, Doubleday, Doran & Co., Inc., 1945.

THE METHYLENE BLUE TEST IN INFECTIOUS (EPIDEMIC) HEPATITIS

CAPTAIN SYDNEY S. GELLIS
MEDICAL CORPS, ARMY OF THE UNITED STATES
AND
JOSEPH STOKES JR, M.D.
PHILADELPHIA

The methylene blue test described by Franke [1] as a method for the detection of bilirubin in urine was used by Stokes and Neefe [2] in an outbreak of infectious (epidemic) hepatitis with results which indicated its possible value in the early diagnosis of the disease In further investigating a modified methylene blue test suggested by Franke and first employed by Fellinger and Menkes,[3] Neefe [4] found the modified test to be of value in determining the presence of biliary pigments in the urine in the preicteric stage of the disease and occasionally before a significant increase in the concentration of total serum bilirubin was found. Because of its simplicity the modified test, although somewhat less sensitive than the Harrison spot test, was employed during the course of an investigation of infectious (epidemic) hepatitis in the Mediterranean theater of operations from November 1944 to February 1945. The present report is confined to data obtained in the study of the preicteric, icteric and posticteric stages of cases of infectious hepatitis with jaundice.



The modified methylene blue test was performed as follows: To 5 cc. of a prebreakfast urine specimen were added 2 drops of an 0.2 per cent aqueous solution of methylene blue chloride. If a green color resulted, more methylene blue was added dropwise and the last drop required to convert the green color to blue was recorded. Pipets were used which delivered 20 drops of the solution per cubic centimeter. Methylene blue chloride proved to be satisfactory in that the dye content of different lots showed little variation. When readings were made by natural light, no difficulty was found in determining the change from a green color to blue. If more than 5 drops were required to produce the color change, the urine was diluted with distilled water and methylene blue was again added drop by drop until the end point was reached. Correction was then made for the dilution factor. This was found to be necessary because the addition of more than 5 drops of methylene blue resulted in a color of such intensity that the end point was difficult to determine.

Methylene blue tests on the prebreakfast urine specimens of 1,000 patients with diseases other than hepatitis gave the following results: Seventy-four per cent of the urine specimens yielded a blue solution after the addition of 2 drops of the reagent, 24.3 per cent required 3 drops and 1.7 per cent required 4 drops in order to convert the resulting green color to blue. Thus in this series of 1,000 patients no urine specimens yielded a green reaction after the addition of 4 drops of the reagent. On the basis of the foregoing results a test of 5 drops or more was considered positive.

Daily methylene blue tests were performed on the morning urine specimens of 77 patients with hepatitis with jaundice. Of the 77, 44 were jaundiced at the time of admission to the hospital and 33 developed jaundice subsequent to the date of admission. The methylene blue test became positive in the 33 patients with preicteric hepatitis one to six days before scleral icterus made its appearance. The exact number of days during which the methylene blue test was positive prior to the appearance of scleral icterus is shown for each case in the accompanying table.

At the time when the methylene blue test first became positive, 12 of the 33 patients had normal icterus indexes while the remaining 21 patients had icterus indexes which were either at the upper limits of normal or were slightly elevated.

Thus from the foregoing data it was possible to suspect hepatitis in 33 patients one to six days before clinical icterus became apparent and in 12 of the 33 patients before the icterus index was elevated.

Methylene blue tests during the preicteric, icteric and posticteric stages

The methylene blue test also proved to be of value in following the course of these patients, in that titration of serial dilutions of the urines served as a rough approximation of the icterus index. However, after the height of jaundice had been reached and the patients' convalescence had begun, the methylene blue test became negative although clinical icterus was present and the icterus index was still elevated. The range of the icterus index in which the test became negative for the 77 patients studied was between 35 and 20 despite the fact that during the preicteric and early icteric stages the test was positive in the presence of a normal or slightly elevated icterus index. To illustrate these findings, the accompanying chart records the methylene blue tests during the preicteric, icteric and posticteric stages of 1 of the patients in the series.

Studies of urobilinogen excretion in these patients were conducted by Major Phillip Hallock and will be reported elsewhere. The results coincided with the findings of the methylene blue test, but the chief advantage of the latter test lay in its simplicity and

the ease with which a large number of determinations could be made.

Of the 77 patients studied, 5 developed relapses characterized by the development of fever, abdominal pain, nausea, vomiting and enlargement and tenderness of the liver. In all 5 the cephalin cholesterol flocculation test which had previously returned to normal became strongly positive again and the methylene blue test likewise became positive. Four of the patients developed no rise in icterus index during the relapse, while the fifth patient became jaundiced for the second time. Thus the methylene blue test in these cases also served to warn of an impending relapse.

COMMENT

In February 1945, when the present studies had been completed, a report on the use of the methylene blue test in patients with liver damage due to tetrachlorethane was published by Myers.[5] In that study the test was performed by adding 2 drops of Loeffler's methylene blue to 10 cc. of urine. If a green color resulted, the test was considered positive; the test was repeated with increasing dilutions of the urine until the dilution was reached in which 2 drops of the reagent produced a blue color. Myers' findings in tetrachlorethane poisoning are similar to our results in infectious hepatitis in that the methylene blue test became positive prior to an elevation of serum bilirubin and subsequently became negative before the return of serum

Cases Showing Positive Methylene Blue Tests Prior to Jaundice

Number of hospital days preceding clinical jaundice	1	2	3	4	5	6
Number of cases showing positive methylene blue tests	7	10	5	6	4	1

bilirubin to normal limits. Thus in liver damage due to tetrachlorethane the methylene blue test permitted the prediction of impending icterus, facilitating the prompt removal of the patient from further exposure to the toxic fumes.

The exact mechanism of the methylene blue test is uncertain. Myers feels that the green color resulting from the addition of methylene blue to bilirubin is due primarily to a mixture of pigments. According to Reinhold,[6] chemical reaction occurs between methylene blue and bilirubin but his studies also indicate that the contribution of this reaction to the development of the green color is less important than is the effect of blending the blue with the yellow bile pigment. There appears to be no explanation at present to account for a negative methylene blue test during the convalescent stage of hepatitis when serum bilirubin is still elevated, whereas the test is strongly positive in the preicteric stage although serum bilirubin may be normal at the time. If the methylene blue test is a measure of bilirubin in the urine, a variation in renal threshold resulting perhaps from alteration in the availability of the bilirubin for renal excretion, or a chemical alteration of bilirubin may account for the foregoing findings. Further investigation will be necessary to clarify these points.

6. Reinhold, J. G.: Personal communication to the authors.

SUMMARY

The modified methylene blue test for bilirubin in the urine employed in a study of infectious (epidemic) hepatitis with jaundice proved of value (*a*) in the early diagnosis of preicteric hepatitis, (*b*) in evaluating the course of the disease and (*c*) in the prediction of impending relapse. Because of the simplicity of the test, it appears most useful in large scale testing during the course of an outbreak of infectious hepatitis and in installations where complete laboratory facilities are lacking.

GAS GANGRENE

A STUDY OF 96 CASES TREATED IN AN EVACUATION HOSPITAL

LIEUTENANT COLONEL FRANCIS H. LANGLEY
Chief of Surgical Service
AND
CAPTAIN LAWRENCE B. WINKELSTEIN
MEDICAL CORPS, ARMY OF THE UNITED STATES

The high incidence of gas gangrene infection in modern warfare and the difficulties encountered in the treatment and cure of the disease have been and still constitute a major medical problem. It has been estimated that the incidence of gas gangrene in the African campaigns of 1942 and 1943 was as high as that encountered in France during the world war of 1914-1918. Although these anaerobic infections were not especially common in the Tunisian campaign (2 to 7 cases per thousand wounded) they were definitely more prevalent in Sicily (10 cases per thousand wounded) and were considered to have been the most troublesome infection encountered in forward military areas during the Italian campaign of 1943-1944 (20 cases per thousand). These figures acquire additional importance when MacLennan and MacFarlane[1] estimate that the case fatality of gas gangrene in the present war has been approximately 50 per cent.

Statistical data are not yet available on the incidence of the disease among those wounded in France. It is known, however, that during the period of September 1943 to and including December 1943 the incidence among the American troops in Italy approximated 6 cases per thousand battle casualties.

The problem of the diagnosis and treatment of gas gangrene is one peculiar to the level of medical care of the evacuation hospital. It is at this level that the disease is first encountered and also at this level that definitive treatment must be devised and executed. Since the operational activation of this evacuation hospital in France we have had the opportunity of studying and treating a larger number of cases of gas gangrene than would normally be seen in a medical unit of this type. The total number of cases of anaerobic gas producing infections treated at the eight different installations of this hospital from July 25 to Dec. 1, 1944 has been 96, which signifies a gross incidence of 9.5 cases per thousand admissions, or a corrected incidence of 16.0 per thousand surgical cases. This figure, although high, does not quite reach the proportions

The entire hospital unit cooperated in this work. Capt. R. E. Hultkrans, M. C., and Capt. E. N. Bookrajian, M. C., of the Surgical Service performed many of the operative procedures. Second Lieutenants Edna May Rutherford, A. N. C., and Angelina Russo, A. N. C., helped in compiling the statistics and gave untiring devotion in the care of the patients.

1. MacLennan, J. D., and MacFarlane, M. G.: Brit. M. J. 1: 683 (May 20) 1944.

(20 per thousand battle casualties) found in the early weeks of the Italian campaign in the British Eighth Army.

Because of this relatively large number, an attempt was made to determine what errors of omission or commission had been made and, if possible, to see what further measures could be taken both to reduce the incidence and to improve the treatment. With this in mind, various studies of our cases, individually and collectively, were made.

STATISTICAL STUDY OF GAS GANGRENE

1. *Incidence.*—In preparation for these studies a statistical review of all cases of gas gangrene diagnosed and treated at the various installations of this hospital in northern France was made. Only such cases as could be positively diagnosed as gas bacillus infections are included, and all questionable or doubtful cases are excluded from the series here reported. These cases, tabulated against the total number of surgical cases treated, are expressed in table 1, a study of which reveals the obviously high incidence of gas gangrene infection among the prisoners of war. These prisoners included not only Germans but also Czechs, Rumanians, Bulgars, Poles, Austrians and some Russians. With this group the incidence per thousand surgical casualties was 51.9, which is over six times the American

TABLE 1.—*Incidence of Gas Gangrene*

	Total	United States	Prisoners of War	Free French	Civilians
Surgical casualties	6,000	4,051	1,040	652	257
Cases of gas gangrene	96	32	54	8	2
Per cent of total cases of gas gangrene	100	33.3	56.3	8.3	2.1
Incidence per thousand surgical cases	16.0	8.0	51.9	12.3	7.8

incidence of 8.0, or four times that of the Free French, which was 12.3. Attempts at explanation of this will be made later. It has been our duty on two occasions to care for many such German wounded, the majority of whom, before their admission, had had no previous therapy other than the simplest of first aid measures. In 1 instance over 380 such prisoners, with all types of wounds, were brought at one time into the hospital, already nearly filled to capacity. These prisoners were taken from a nearby German sanatorium where neither doctors nor medical equipment were available. There resulted a tremendous backlog for surgery, and many of these wounded had to remain for several days before they reached the surgical tents. At the same time our incidence of gas gangrene reached its peak, with 22 confirmed cases within a period of three days. At another installation the relationship of German casualties, as compared with those of the combined American and French injured, was 2 to 1. At this time 386 surgical cases were completed in a period of less than four days. The incidence of gas gangrene at this time was 11 cases among the prisoners of war, 1 case in a French soldier and none among the American wounded.

2. *Criteria for the Diagnosis of Gas Gangrene.*—Many patients admitted to the hospital were already patently infected with gas gangrene at the time of admission. As our series of cases grew, we were able to establish various criteria for diagnosis so that these potentially dangerous cases could get surgical priority. The criteria for a tentative diagnosis of gas gangrene at admission or preoperatively was as follows:

1. History of:
   (a) Pain, especially with a feeling of tension, heaviness or tightness of the dressing. This was the most frequent and the most striking complaint and was present in almost 100 per cent of the cases in which an early diagnosis was made.
   (b) A clinical degree of toxemia, often coupled with definite mental changes. This was noticed in about 75 per cent of the cases admitted and varied greatly in degree and depth.
   (c) In more advanced cases a typical change in general skin color. This varied from an extreme pallor with a bluish brown tinge to a semibronzing not only of the skin around the wound but also of the face, the lips and the body in general.
2. A high pulse rate, usually over 110 and frequently above 120, out of proportion to either the degree of infection present or the degree of toxemia.
3. Elevation of temperature. A majority of those wounded in battle admitted to the hospital had normal or subnormal temperatures as a result of the inhibitory effect of early sulfonamide therapy. In all of the suspected gas gangrene cases the temperature was elevated regardless of sulfonamides, usually from 100 to 102 F. Here also the elevation of temperature was much higher than would be suggested by the degree of infection or toxemia.
4. Anemia, with a tendency to increase in severity. This usually was out of proportion to the amount of hemorrhage but in definite relationship to the length and severity of the toxemia.
5. The wound:
   (a) An odor, best described as "rotten or decaying meat" or "mousey," and entirely different from the odor of other gross infections or contaminations. This typical odor was present in only about a third of the cases which were diagnosed on admission. In the remainder it was either absent or was masked by the odor of Escherichia coli or other putrefactive organisms.
   (b) In early cases no remarkable change around the area of the wound. The crepitus, so often described was noted in only a few cases. Similarly the textbook description of the mottling or bronzing of the skin at the edges of the wound was not noted frequently. A few cases of subcutaneous, well demarcated edema were seen.

Tentative diagnosis was not made on any one single finding but rather on the correlation of several findings. With each such tentative diagnosis every attempt was made to get the patient in the best possible physical condition for surgery at the earliest possible moment, where the diagnosis was either corroborated or disproved.

It must be understood that under conditions such as are found in an evacuation hospital, and with only limited laboratory facilities available, the absolute diagnosis of clostridial infection is impossible. For similar reasons it has been impossible to classify the various types of anaerobes which are virulent gas formers. Final diagnosis was made by the gross appearance of the wound at surgery (at least two surgeons concurring) together with the clinical preoperative and postoperative course and laboratory findings. The criteria for diagnosis before and at surgery, and for determination of further therapy, consisted of:

1. Clinical course of the patient between admission and operation: Increases in pulse rate, temperature and degree of toxicity, with special emphasis on the last mentioned.

2. X-ray findings: X-ray facilities were of the best, and it was not infrequently that the radiologist reported gas shadows along muscle planes, other than shadows of imprisoned air, in his routine radiographic reports. X-ray evidence of gas was never used, however, for other than supportive information.

3. Microscopic examination of muscle smear: Thorough, careful and precise studies of muscle and exudate smears, stained by the Gram method, were made in every case. The pathologist examining these smears exercised most conservative judgment in pronouncing them to be positive. All doubtful specimens were considered negative. No case with "negative" smears, regardless of other findings, was considered to be gas gangrene.

4. Appearance of the wound at operation: Characteristic color changes and crepitation were not often found. What was noted frequently in all positive cases was a typical subcutaneous edema, which was present around the site of the lesion and which spread outward from that area in a rather well demarcated zone. Gas bubbles were found often but alone were not considered diagnostic unless they were more than localized and were present in the muscle planes. The most characteristic finding, however, was the typical picture of the muscle tissue itself. The muscles seemed to be affected individually and characterized by death of the tissue, an edematous appearance and color changes varying from a deep dirty brown through a green to a gray.

3. *Time of Diagnosis.*—Accordingly, with the foregoing classification as a basis, the diagnosis of gas gangrene was made at one of three stages in the clinical course of the patient: (1) on admission or soon after, (2) at the time of operation and (3) postoperatively. The result of this classification is expressed in table 2.

Thus, briefly, we were able to diagnose tentatively one third of all our cases of gas gangrene either at the time of admission to the hospital or shortly thereafter. With increasing experience, more and more cases are being thus classified. All these were later confirmed at operation. Similar tentative diagnoses were made in approximately 15 other cases, which, however, were later disproved. Of the total number 57.4 per cent were diagnosed for the first time at operation. Seven cases, or 7.3 per cent of the total number, either were misdiagnosed when the original débridement was done or the infection developed in these cases subsequent to surgery.

4. *Age and Sex Incidence.*—All cases reported here are in males. The youngest, aged 17, and the oldest, aged 44, were both prisoners of war. The average age for the entire group was 26.2 years. All patients were apparently in good physical condition at the time the injuries were received, nor was there any evidence of long standing malnutrition, avitaminosis or systemic disease present even in the captured Germans.

TABLE 2.—*Time of Diagnosis of Gas Gangrene*

	United States	Prisoners of War	Free French	Civilians	Total	Per Cent of Cases
Gas infection diagnosed as presumably present when first seen	6	27	1	..	34	35.4
Gas infection diagnosed at operation (not including the preceding, which were confirmed at this time)	20	26	7	2	55	57.4
Gas infection developing postoperatively	6	1	..	..	7	7.2
Total	32	54	8	2	96	100.0

5. *Agents.*—All infections included in this series in which gas gangrene developed, save 1, were the results of battle casualties. Of the total of 96 cases 48 cases, or 50 per cent, were the direct result of mortar or other high explosive shells; 17 cases, or 17.7 per cent, occurred subsequent to mine detonations; 10 cases, or 11 per cent, were due to booby trap explosions, and the remainder were due to gunshot wounds. The 1 case which was not a battle casualty occurred in a French civilian who received his injuries as the result of a fall from a fast moving motorcycle.

6. *Effect of Delay in Treatment.*—We have further attempted to determine what effect delay in first aid and delay in hospital treatment and surgery might have on the ultimate production and severity of gas gangrene. MacLennon [1] thinks that the disease develops so soon after wounding and runs so swift a course that delays and difficulties of treatment in the field are not the principal reason for its high incidence and mortality. However, this opinion is not commonly held. A thorough individual interrogation of 73 of the total number of 96 patients was made to determine the effect of this time relationship and was directed along the following lines: Questions were asked each patient concerning the exact time the wound occurred, the type of dressing applied and whether sulfonamides were used according to present army directives. The answers, in general, were definite and accurate, and data thus obtained were correlated with the emergency medical tag, the time of admission to the hospital and the time surgical operation was performed. This was tabulated, as previously, according to nationalities and contrasted with the incidence per thousand surgical cases, as determined in table 1. The data are set forth in table 3.

The shortest lapse of time between initial injury and the development of a true, severe gas gangrene infection occurred in an American soldier who, when operated on only six hours after having received a severe lacerating wound of the right thigh, was found to be thoroughly infected with the organisms. This case is to our knowledge the earliest case of gas gangrene reported. The longest time lapse between injury and surgery was in a German prisoner who lay wounded and unattended for thirty hours and who did not reach

the hospital until four days after injury. It was necessary to treat him medically for three additional days before operation could be performed because of his poor physical condition.

Actually we have not been able to determine over our entire period of activity the average time for cases in which gas infection did not develop to reach operation. As in the cases of those which did, this time lapse in the hospital was dependent on our backlog. Sample tests at the various installations, however, point to the fact that this delay was in excess of eighteen hours.

While the entire period from wounding to débridement is of vital importance in the development of gas gangrene, there can be no question that the time between the occurrence of the injury and the application of the initial dressing is the critical period. This is well exemplified by the present study. This average initial time lapse for the American wounded was twelve minutes, for the Free French eighteen minutes and for the prisoners of war five hours and forty minutes. It is during this period when the wound lies open, in contact with clothing, dirt and soil, that the infection is most likely to be introduced.

Similarly, this is reflected in the time interval which occurred between wounding and arrival at the hospital. An average of fifteen hours elapsed before Americans and French were admitted, while 42.6 hours passed before Germans were delivered to the hospital.

Further study of table 3 shows the same trend while at the hospital itself. The average length of time from injury to operation in the American and French groups was one and one-half days, in the prisoner of war group three and three-fourths days. The peak of American and French operations for gas infection was between one and two days after wounding, whereas in the German group, in which the delay was longer, it occurred between three and four days after wounding This in no way can be thought of as discrimination against the Germans. The delay here was necessarily greater because, in general, the Germans already showed more manifest signs of toxemia and cachexia and most of them needed considerable therapy before being able to withstand surgery. The importance of delay in both initial and definitive treatment is evident when a comparison of the prisoners of war group, with an incidence of 52 per thousand cases, is made with the incidence of 8.0 per thousand cases in the American group.

7. Early Use of Sulfonamide Compounds.—The higher incidence in the German group at one time was thought to be due to the absence of the initial use of the sulfonamides both locally and by mouth. After questioning a number of gas gangrene infected prisoners we were surprised to note that the number of Germans who received sulfonamide therapy from the very beginning almost equaled the number of Americans. All of the former received initial care by American Medical Aid men. All patients received sulfonamides at the hospital. Table 4 demonstrated the result of questioning along these lines.

Since, then, general health factors being equal and sulfonamides being used almost equally in the Allied and German groups, the main factor which could be proposed as having an effect on the development of gas gangrene is the time lapse between wounding and both initial therapy and definitive surgery.

Another factor has recently been noted which may in part also explain the greater incidence of gas gangrene among the prisoners of war. This is the observation, made at operation, that the wounds in this group of patients were much more highly contaminated by shreds and even large pieces of woolen clothing than were the wounds of either American or French soldiers. In checking this we have found that all the garments of the Germans in general showed greater evidence of wear, a greater friability and a much looser nap.

8. Types of Wounds.—Regardless of the gas infection, all wounds were classified as "severe" in the amount of damage produced. Twenty-eight (29 per cent) were of the penetrating type, with metallic fragments present in the tissue; forty-one (43 per cent) were of the perforating type, and the remainder (twenty-seven, or 28 per cent) were lacerating in character. Compound comminuted fractures were present in fifty-six (58 per cent) of all injuries.

9. Location of Infection.—We have analyzed all the injuries in which gas infections developed and divided them into five categories according to location: (1) shoulder, (2) upper extremity (which includes the upper arm, the forearm, the wrist and the hand, (3) buttocks, (4) thigh and (5) lower extremity (which includes the calf, ankle and foot). Multiple wounds were common (60 per cent), but for the purpose of this discussion only wounds infected with gas gangrene are considered. In only 1 case in which multiple wounds were present was gas bacillus infection present at more than one place. A study of all operative diagnoses over the four months of activity was made according to the listing given and the incidence of each type

TABLE 4.—*Sulfonamide Therapy Before Hospitalization*

Thigh	940	35	36.5	37.2
Lower extremity	1,201	9	9.4	9.7

of wound determined. Similarly the incidences of gas gangrene for the several locations were computed. These interesting statistics are presented in table 5.

By making a classification of all such cases of infection with gas gangrene, and by comparing these with the total number of injuries which have been classified similarly, the sites of predilection for the development of the disease were determined. Thus, while wounds of the buttocks made up slightly less than a third of our series, the incidence of gas infection in buttock injuries was 55.4 per thousand. A like finding is recorded in the case of wounds of the thigh, in which the incidence was 37.2 per thousand. On the other hand, wounds of the shoulder, the upper extremity and the lower extremity below the knee are less commonly infected. We have not, in this hospital, encountered any cases of primary gas bacillus infection of the neck, head, abdomen, back or perineum. Three cases were noted in which gas infection was present in a wound of an extremity and had spread to the trunk.

TREATMENT OF GAS GANGRENE INFECTION

The treatment followed in this series of cases is essentially that which is outlined in U. S. Army Circular Letter No. 178. Many modifications were and still are being made, and attempts at improving our technic and mortality rate are constantly being tried. These modifications and changes are reflected in the constantly decreasing mortality and morbidity as we have proceeded from one installation to another. For example, in our last installation there was only one death in 22 cases, and the average time for evacuation of gas cases was only slightly longer than for the average case without infection. This may be compared to our first setup, in which there was a mortality of 1 in 6 cases and the evacuation time was several days longer than for the average.

Treatment was divided into three stages, the preoperative, operative and postoperative. It was further classified as specific and nonspecific, the specific consisting of the use of penicillin and gas gangrene antitoxin, employed by various methods and utilizing various routes of introduction. Nonspecific measures consisted of general supportive treatment and the use of whole blood, blood plasma and sulfonamides.

1. *Preoperative Treatment.*—During periods of extreme activity, abdominal, chest and brain injuries received priority in surgery. However, when a preoperative diagnosis of gas gangrene infection had been made, regardless of the location of the wound, that case was also given the highest priority rating. The main essential of preoperative care was preparing the patient for débridement as quickly and as completely as possible. General supportive measures, treatment of shock and elevation of the blood count to as near normal as possible were considered to be of primary importance before the patient was ready for operation.

As is well known, the anemia resulting from gas gangrene toxemia is severe. We have noted repeatedly that when the blood count before operation was above 3.5 million, with a correspondingly high hemoglobin value, the traumatic shock occurring from extensive débridement was not as great as when lower blood values were present. We further noted that the patient was returned to the postoperative ward in better general condition, and postoperative therapy was greatly facilitated, when the blood picture approached normal before operation.

Thirty-one patients of this series were admitted to the hospital in shock. Excluding these, whole blood in quantities of from 500 cc. to 2,000 cc. (average 875 cc.) was administered preoperatively to 41 of the 65 remaining patients. Similarly, blood plasma in amounts ranging from 250 cc. to 750 cc. was given to 53 patients (average 400 cc.). Routine blood counts were not made preoperatively but are available for 23 cases. The average for these was a red blood cell count of 3.77 million with a hemoglobin (Tallqvist) of 80.5 per cent either after transfusion had been completed or immediately before operative procedures were started.

Sulfadiazine or sulfathiazole was administered by mouth routinely to all patients, starting with an initial dose of 2 Gm. and continuing with 1 Gm. every four hours. No basic difference was noted in the effects of these two compounds. Medication was continued up to the time the patient was admitted to surgery, and also routinely postoperatively until the patient was evacuated. The amount of sulfonamide drug varied from 3 Gm. minimum to 31 Gm. maximum. The average dose for the 96 patients was 10.2 Gm. preoperatively. No demonstrable effect of the sulfonamide compounds could be observed either in preventing the onset or in limiting the spread of the gas bacillus infection. Its general efficacy against other wound contaminants was easily recognized.

The sodium salt of penicillin was also used routinely postoperatively and was administered by intramuscular injection only. If, for any reason, operation had to be delayed, all patients with wounds of the buttock, thigh and perineal regions received 40,000 units every four hours. More recently we have given 20,000 units at two hour intervals, because when given in smaller and more frequent doses the blood level remains higher. All patients with other extremity and trunk wounds received 20,000 units every four hours. When gas gangrene had been tentatively diagnosed, the patient received the larger dosages regardless of the location of the wound. The smallest dose administered preoperatively was 20,000 units, the largest 960,000 units. The average amount of penicillin given preoperatively was 220,000 units. Although there was no way of determining exactly, we have not felt that penicillin per se had any major effect preoperatively in preventing the infection, in decreasing its severity or in preventing its spread.

The use of gas gangrene antitoxin preoperatively has not proved very successful in our hands. Arbitrarily, eighteen therapeutic doses were given in 4 cases in which it was thus used. In these cases, no appreciable change was observed; the toxicity was not relieved, nor was the postoperative course affected favorably in any manner. In 1 case a pronounced sensitivity to the serum developed, and it was necessary to desensitize the patient before more of the antitoxin could be given postoperatively. Furthermore, adequate or complete dosage could not be determined, as we were able to do postoperatively in a large number of cases. Therefore, since we felt that as it was not efficacious preoperatively, and since a certain amount of unnecessary harm could be done by administering large amounts of foreign protein [illegible] injection of antitoxin before operation was discontinued.

2. *Operation.*—We have confirmed, and it is not possible to overemphasize the fact, that early surgical débridement is the one single measure of vital impor-

tance in the prophylaxis as well as the treatment of gas gangrene. That such treatment should be completed as early as possible after the wound has occurred is demonstrated in table 3. Furthermore, we have noted repeatedly that, when operation was delayed for long periods the toxicity postoperatively was both deeper and prolonged and that the degree and intensity of the morbidity was likewise increased. We have estimated that the average time for all gas gangrene patients, regardless of nationality or the press of large numbers of patients to reach operation, after wounding was 3.1 days from the time that they were wounded. In order to emphasize the effect of this delay, in six of the eleven deaths which occurred directly as the result of gas gangrene the average wait before operation was longer than 5.2 days.

Not only is early surgical intervention important but also a thorough complete débridement of the wound is essential in the successful treatment of the disease. Reports of case histories of gas gangrene in the closing year of World War I have demonstrated this. Similarly a private communication from one of the nurses stationed at Corregidor prior to its fall in 1942 stated that gas gangrene was being handled quite successfully by extensive débridement and that neither sulfonamides, penicillin nor in many cases whole blood was available.

In accord with the best surgical principles, we have found that in operating on patients with patent gas gangrene, all foreign bodies, metallic as well as nonmetallic, such as splinters, pieces of clothing and dirt, had to be removed to prevent recurrence. Likewise, all damaged and infected muscles or muscle groups had to be cut away. Counterincisions to promote aeration and drainage have been employed more and more. From time to time, in hopes of saving a badly injured extremity, amputation was held off in spite of definite interference with blood supply. This was justified by the saving of an appreciable number of limbs. However, in a few cases in which the circulation was inadequate and moist gangrene supervened, pockets of gas infection were found at the time of amputation. Such cases constitute 3 of the 6 instances in which gas gangrene developed subsequent to primary operation. The importance of thorough débridement and likewise the secondary role of the chemotherapeutic agents with grossly incomplete operation is well exemplified by the following case:

CASE 34.—A private first class was wounded by a shell burst and shrapnel fragments on Oct. 6, 1944 at 10 a. m. Five minutes after he received his injury the wounds were dressed by medical aid men but no sulfanilamide powder was introduced. Sulfadiazine 3 Gm. was taken by mouth. The injuries consisted of extensive and numerous penetrating wounds of the right thigh, leg, foot and also the right arm. These wounds were complicated by compound comminuted fractures of both the right fibula and the right radius. Plasma 500 cc. was administered between the time the wound was dressed and 8 p. m., when he was received at this hospital.

During the twelve hours he remained in the preoperative ward he received 1,000 cc. of whole blood, 500 cc. of plasma, 5 Gm. of sodium sulfadiazine intravenously and 120,000 units of penicillin intramuscularly. Extensive débridement of all wounds was carried out at 8 a. m. October 7, twenty-two hours after being wounded. At this time the circulation of both the leg and the arm was good. Many pieces of shrapnel were removed and much muscle tissue was excised, but no suspicion of gas infection was noted. Because of the vastness of the injury the surgeon felt that the débridement was incomplete.

On the evening of the second postoperative day the soldier complained of severe pain in the right foot and leg. The temperature and pulse rate, which previously were normal, began to rise the following morning.

At 9 p. m. October 10 he was taken to the operating room for inspection of the wound. At this time moderately extensive evidence of gas gangrene (gas bubbles, myositis and edema) was found in the right thigh. Muscle smears at this time were positive. Amputation was performed above the level of the infection. The condition of the wound of the arm was good. Between the first and second operations he received 960,000 units of penicillin, 31 Gm. of sulfadiazine, 500 cc. of whole blood and 500 cc. of plasma.

There is no question that because of the extensiveness of the leg wound and because of the inability of the operator to remove all necrotic and dead tissue the gas infection was able to spread. Notes of incomplete débridement because of poor physical condition or because of critical systemic complications in the general condition of the patient were made in 2 other of the 7 cases in which gas gangrene developed postoperatively.

Routinely, approximately 5 Gm. of sulfanilamide crystals was dusted into wounds after the operation was completed. The maximum employed was 7 Gm., the minimum 4 Gm. We have found, as have others, that it was necessary only to dust the wound and that larger amounts caked and prevented drainage.

At the onset of this study, penicillin was not used routinely at the site of the injury. It was not until approximately two thirds of this series was completed that penicillin was used locally at the time of operation. We had felt that the rapidity of absorption of this drug was so great that local use was of no great importance. However, since dusting penicillin into the wound has become routine we have found that the length of postoperative morbidity has been decreased and that the postoperative course has been less stormy. It may be conjectured, since the gas bacillus grows in dead or dying tissue where the blood supply is absent or minimal, that penicillin given systemically cannot reach the infected area but that by local use the direct effect of the drug is utilized. When penicillin was employed locally it was mixed with the sulfanilamide before being placed in the wound. Twenty-two cases were thus treated with doses of from 33,000 units to 100,000 units dusted in the wound.

3. *Postoperative Treatment.*—Practically as important as the actual procedure was the care and therapy of the patient after reaching the postoperative ward. Treatment had to be carefully balanced between the condition of the patient and the amount of medication necessary.

Sulfonamides were used routinely in doses of 1 Gm. every four hours by mouth, or comparable doses intravenously when the oral route was not available. Although we, as most others,[2] feel that the sulfonamides have no effect against the clostridial organisms, they have a definite place in the therapy of gas gangrene because of their bactericidal or bacteriostatic effect on other virulent and putrefactive organisms. Sulfadiazine was given preference over sulfathiazole, since fewer side reactions were encountered, and was continued rou-

2. Hac, L. R., and Hubert, A. C.: Proc. Soc. Exper. Biol. & Med. 52:61, 1943. McKnight, W. B., Loewenberg, R. D., and Wright, Virginia L.: Penicillin in Gas Gangrene, J. A. M. A. 124:369 (Feb. 5) 1944.

tinely from the time the patient was returned from operation until he was evacuated or until special orders for discontinuance were written. The minimum dose postoperatively was 8 Gm. given to 2 patients who died within twelve hours of operation; the maximum was 60 Gm. The average amount administered was 26.3 Gm.

The most consistent characteristic effect of the toxemia resulting from the infection was the severe anemia produced in all cases. Eventually we discarded several cases from this series because both the toxemia and the anemia were absent. To our mind, both these factors must be present to verify any diagnosis of gas gangrene. This anemia was particularly severe and very difficult to combat. The average postoperative blood count was slightly under 3 million red blood cells per cubic millimeter, with a corresponding hemoglobin average of 62 per cent. Counts as low as 1.5 million were not exceptional. It was necessary to use whole blood in large amounts and at frequent intervals to combat this anemia. Over the entire series an average of 2.7 transfusions of 500 cc. of citrated blood was given. The maximum administered was 5,000 cc. over a period of seven days. Transfusion reactions were more common but not more severe with these patients than with average cases throughout the hospital. In general these consisted of mild to severe chills, with various degrees of hyperpyrexia, urticaria and in 1 case hemoglobinuria and oliguria. All such reactions subsided with appropriate therapy.

Furthermore it was noted that the result of a single transfusion was not nearly as permanent as might be expected. Increases in blood counts and hemoglobin noted a few hours after having received blood were almost obviated twenty-four hours later. This was not nearly as pronounced when the severity of the toxemia abated and may be interpreted as being due to the increased hemolytic effect of the toxins on blood cells, whose fragility may have been increased by standing in vitro.

The specific treatment of gas gangrene infection consisted in the active and aggressive use of penicillin and gas gangrene antitoxin, the former for its action against the organism themselves and the latter for overcoming the toxins produced by them. From the very beginning of this work our observations pointed to the fact that penicillin was active in combating clostridial infections only after débridement had been completed and when minimal foci were present. As our experience increased we felt more and more strongly that the amount of penicillin necessary to combat the infection successfully was insufficient and had to be increased. With the first half of this series an average of 480,000 units was given postoperatively, whereas in the second half an average of 730,000 units was administered. Several patients received as high as 1,200,000 units. At first this was all given intramuscularly. To provide a more rapid increase in the blood level we have recently begun to use penicillin intravenously, independently of the intramuscular route, in doses of 40,000 units together with the intravenous administration of gas gangrene antitoxin, as described in subsequent paragraphs.

Gas gangrene antitoxin was administered to 82 of the 96 patients in doses of from one to forty-four therapeutic doses. The term "therapeutic dose" is used to signify the amount of trivalent gas gangrene antitoxin which contains 10,000 units each of the antitoxins for Clostridium welchi and Clostridium septicum together with 1,500 units of the antitoxin for Clostridium oedematiens. Although Army directives state that eighteen therapeutic doses should be administered in every case, we have modified this procedure and attempted to regulate the amount given by the degree of toxemia. In our experience the antitoxin per se did not seem to have any inhibitory effect on the organisms themselves but was very efficacious against the toxins produced by the infection. To illustrate this the following case history is quoted:

CASE 54.—A private first class was wounded at 4 p. m., Nov. 9, 1944. The wound was dressed with sulfanilamide powder about ten minutes later. Sulfadiazine 3 Gm. was also taken by mouth. The patient was transferred to this hospital at 12:55 p. m. November 10. A tentative diagnosis of gas gangrene infection in a severe penetrating wound of the left thigh was made on admission.

Preoperatively he received 160,000 units of penicillin and 9 Gm. of sulfadiazine. At operation, ten hours after admission, an extensive débridement, with removal of many large metal fragments, was performed. Considerable devitalized, gray, necrotic and edematous muscle tissue was removed. Both muscle and exudate smears were positive. Two counterincisions, one on the medial and one of the posterior aspect of the thigh, were made to insure adequate exposure and drainage; 33,000 units of penicillin and 5 Gm. of sulfanilamide were dusted into the wound.

The patient was returned to the ward in a highly toxic and irrational state. His temperature was 103 F., pulse rate 180, hemoglobin 55 per cent, red blood cell count 2.7 million. Five hundred cc. of whole citrated blood was given, which was followed by an intravenous drip of nine therapeutic doses of gas gangrene antitoxin together with 40,000 units of penicillin over a period of three hours. A severe, generalized urticaria developed but the mental cloudiness partially disappeared. Following this another 500 cc. of blood was given and then another nine therapeutic doses of gas gangrene antitoxin together with 40,000 units of penicillin. Outside of an increase in the urticaria, the condition of the patient improved remarkably. He became mentally normal and the temperature dropped to 99.8 F. but the pulse rate remained high.

Antitoxin one therapeutic dose was given intramuscularly every twelve hours for four doses. Penicillin was also administered intramuscularly in doses of 20,000 units every two hours for a total of 480,000 throughout the entire time. Two transfusions totaling 1,000 cc. of whole blood were also given. Forty-eight hours after the intravenous antitoxin was completed the pulse rate and temperature rose and the patient was returned to the operating room for inspection of the wound. No change in the mental state was noted. On examination, a subcutaneous crepitus was present which extended to the axilla. Extensive longitudinal incisions were made and débridement of the infected tissues was carried out. Since he was moderately toxic on return to the ward it was necessary to give eighteen additional therapeutic doses of gas gangrene antitoxin intravenously over a period of six hours. These completely controlled the toxic state. He was evacuated on the seventh postoperative day. A total of forty therapeutic doses of antitoxin, 3,000 cc. of whole blood, 960,000 units of penicillin intramuscularly and 120,000 units intravenously and 31 Gm. of sulfadiazine were administered. Recovery from gas infection was complete as far as known.

Thus it is obvious that the antitoxin was able to control the toxemia in this case despite the fact that the organisms were still present and active in the wound. Likewise, despite the administration of the antitoxin, the organisms themselves were not inhibited. This was noted in all our cases which, when diagnosed

at the time of operation, required further operative procedures because of the spread of the infection. Such striking effect of antitoxin therapy did not occur in every case, but in a large majority we were able actually to gage the amount necessary by the response to the drug. If no untoward reactions developed with its use we usually considered eighteen therapeutic doses to be a minimum. However, no figure can be given for the total dosage which may be necessary to neutralize the toxin.[1] The following case summary illustrates the manner in which we have attempted in general to judge the amount of gas gangrene antitoxin necessary:

CASE 73.—A prisoner aged 42 presumably was wounded several days before he was picked up by American troops at 2:35 p. m. Sept. 14, 1944. There were dirty dressings covering multiple penetrating wounds of the left buttock and thigh, which were complicated by a severe compound comminuted fracture of the left femur. Wounds of the right calf and right foot also were covered with dirty dressings. All injuries were dusted with sulfanilamide and redressed, and 3 Gm. of sulfadiazine was given by mouth. Plasma 250 cc. also was administered at this time. He was evacuated to this hospital at 12:20 a. m. September 15.

On admission a blood pressure of 68/40 was recorded. Diagnoses of severe shock and of extensive gas gangrene of the left lower extremity were made. The patient was extremely toxic and irrational. The red blood cell count was 2,100,000. Hemoglobin was 50 per cent. Despite the administration of large amounts of fluid intravenously it was impossible to raise the blood pressure to normal limits for any length of time. During the forty-eight hours of preoperative therapy he received 2,000 cc. of whole blood, 2,000 cc. of plasma, 2,000 cc. of glucose 5 per cent in saline solution, 15,000 units of tetanus antitoxin, 440,000 units of penicillin and 8 Gm. of sodium sulfadiazine. Because of increasing coma and toxemia, and because of decreasing resistance, it was decided that operation was necessary, in spite of the precariously low blood pressure.

The patient was admitted to the operating room at 4 a. m. September 17. A high guillotine amputation of the left thigh was performed because of extensive loss of bone and extensive gas gangrene in the entire thigh and calf. Gas was found to extend into the abdominal wall above Poupart's ligament and to the entire left buttock region. Five hundred cc. of whole blood, together with 500 cc. of blood plasma was given during the amputation. Because the condition of the patient was becoming more and more critical, only counterincisions were made in the calf and buttock without any major débridements being carried out. Six Gm. of sulfanilamide was dusted into the wound.

On return to the gas gangrene isolation tent the blood pressure was 70/50 mm. of mercury, the red blood cell count 2,000, hemoglobin 50 per cent and temperature 104 F. The patient was toxic and irrational and appeared to be dying. One thousand cc. of whole blood followed by 500 cc. of plasma was introduced under pressure. This was followed by nine therapeutic doses of gas gangrene antitoxin in 700 cc. of saline solution. No appreciable change was noted, and another nine therapeutic doses of antitoxin were given over a period of three hours. The temperature dropped to 102.2 F. and the blood pressure remained constant at 70/50. At this time the patient seemed to be slightly less irrational and also seemed to be resting quietly at times.

Fifteen hundred cc. of blood and 500 cc. of plasma were again given, followed in turn by twelve additional therapeutic doses of gas gangrene antitoxin in 1,000 cc. of saline solution and glucose 5 per cent. Four hours after this was completed there was a noticeable change in the condition of the patient. The mental state appeared more normal, actions became purposeful and there was a general diminution in the toxemia. The pulse rate was 110, blood pressure 80/60, red blood cell count 2,800,000, hemoglobin 62 per cent and temperature 99 F. Since the patient had not urinated, catheterization was done and 100 cc. of thick viscid urine containing many red blood cells and 3 plus albumin was removed.

During the next twelve hours four additional therapeutic doses of gas gangrene antitoxin were given followed by 1,000 cc. of blood. Despite the facts that the blood pressure still remained at 90/60 and the anuria continued, the general condition of the patient seemed to be improving. To combat the faulty kidney function 500 cc. of 10 per cent glucose was given intravenously throughout the day. One hundred cc. of 50 per cent glucose and aminophylline in 10 cc. doses were also given twice during the twenty-four hour period.

On the third postoperative day the patient was decidedly edematous and began to show signs of uremia. Urinary function was not resumed and the patient died on the fourth postoperative day. During this entire period he received thirty-four therapeutic doses of gas gangrene antitoxin, 960,000 units of penicillin, 15 Gm. of sodium sulfadiazine, 500 cc. of blood plasma, 3,000 cc. of whole blood, 500 cc. of 10 per cent glucose, 300 cc. of 50 per cent glucose and 30 cc. of aminophylline.

Postmortem examination revealed signs of uremia, pulmonary edema and generalized anasarca. No evidence of gas gangrene was found in the amputation stump, and only old necrotic muscle tissue, with no gas involvement, was found in the other wounds.

It is our opinion that death here resulted from uremia following kidney failure which was secondary to the prolonged period of shock, and that, had the patient been able to overcome the anuria, he would also have overcome the gas gangrene infection.

Reactions to the horse serum, despite negative intracutaneous and ophthalmic tests, were common and were noted in 75 per cent of all our cases. These reactions were manifested by urticaria, chills and fever. We felt that because of the severity of the disease itself, as compared with the mildness of the reactions, they were not sufficient indication for cessation of therapy. This was proved repeatedly by experience, and we have felt justified many times in continuing the infusions despite the presence of these untoward effects. However, one severe anaphylactic reaction did occur. This manifested itself by severe respiratory embarrassment, dyspnea, orthopnea, cardiac irregularity with gallop rhythm, cyanosis and, three hours later, death. Epinephrine, ephedrine and aminophylline in large doses intravenously and intramuscularly were not effective. The reaction occurred after approximately 10 cc. (one-half the therapeutic dose) of the antitoxin had been administered.

The following briefly is the general procedure which we have developed, which has proved in our experience to be the most efficacious in the treatment of gas gangrene postoperatively:

1. Sensitivity test for horse serum immediately on return to postoperative ward, 0.1 cc. of undiluted serum intracutaneously and 0.1 cc. of a 10:1 dilution intraconjunctivally.

2. Nine therapeutic doses of gas gangrene antitoxin in 700 cc. of isotonic solution of sodium chloride as a continuous intravenous drip over a three hour period; 40,000 units of penicillin introduced through the rubber tubing at the start of infusion. A rest period of from three to four hours to observe the effect of the antitoxin. If anemia is present, 500 cc. of whole blood to be transfused at this time.

3. Repetition of 2 until signs of toxemia begin to abate. No limit has been set on the number of therapeutic doses of antitoxin to be administered.

4. Penicillin 20,000 units every two hours together with sulfadiazine 1 Gm. every four hours or, if the oral route is not available, 10 to 15 Gm. of sodium sulfadiazine intravenously per day. A minimum of 720,000 units of penicillin, not including that given intravenously, should be completed by the intramuscular route before therapy is completed.

5. One therapeutic dose of antitoxin every twelve hours intramuscularly after the completion of the intravenous therapy for a minimum of four injections.

6. Hemoglobin, red blood cell count, hematocrit, intake and output checked daily; whole blood as necessary.

Criteria of Cure.—In many cases it was difficult to evaluate a cure because it was often necessary to evacuate patients before we were sure that the disease was completely eradicated. Criteria therefore were limited to examination of the wounds to determine if further extension had taken place or to see if the wound was clean. Besides this, temperature and pulse had to be normal and all evidences of toxemia eliminated. Muscle smears were not made at time of inspection of the wound.

Mortality.—As has been stated, we have attempted to maintain a rigid and high standard of diagnosis. To the best of our medical and surgical knowledge all patients in this series treated for gas gangrene infection actually were infected with a virulent form of the disease. Likewise "prophylactically treated" cases or doubtful cases are eliminated from the scope of this discussion.

In an evacuation hospital, patients are rarely kept for long periods of time, but they are evacuated as soon as the surgeon considers them to be transportable. For this reason, and also because of the military situation, it was often necessary to evacuate patients before a definite cure could be determined. However, follow-up cards were included in each jacket as the patient was evacuated. The cooperation of medical officers in rear echelons has been excellent, and all cards of cases in which the outcome was doubtful have been completed and returned.

TABLE 6.—*Postmortem Findings in 15 Cases*

	Cases
Death due to anaphylaxis and serum reaction, gas gangrene still present in tissues	1
Death due to peritonitis from intestinal wounds, gas gangrene not found post mortem	2
Death due to traumatic irreversible shock, gas gangrene not present post mortem	1
Death due to anuria following profound prolonged irreversible shock, gas gangrene not present post mortem	1
Death due to uncontrolled gas gangrene infection (4 cases proved post mortem)	10

To the best of our knowledge, 15 patients of the entire series of 96 have died. Postmortem examinations were completed in about one half of these cases. When a postmortem examination was not made, the death was classified as being due to gas gangrene. A summary of these postmortem findings is included in table 6.

Thus, no pathologic evidence of gas gangrene could be found in 4 of the total of 15 cases in which death occurred after treatment for gas gangrene infection. All of these cases had complete anti-gas gangrene therapy before death. They can therefore be deleted, thus making the mortality rate for the series of 96 cases 11.5 per cent.

COMMENT

Various interesting data have been derived from this statistical and therapeutic discussion of a series of 96 cases of "clinical gas gangrene" treated in an evacuation hospital in northern France during the four months beginning July 25 and ending Dec. 1, 1944. An incidence of 16.0 cases per thousand surgical admissions with a mortality rate of 11.5 per cent has been noted. These cases represent not only American but also Free French, French civilian and prisoners of war casualties.

With the criteria for the diagnosis of gas gangrene, both preoperatively and at the time of operation, that have been outlined, as a basis, 35.4 per cent of our cases were diagnosed before reaching the operating room; 57.4 per cent were first noted at the time of operation; the remaining 7.2 per cent developed the infection postoperatively.

The highest incidence of gas infection (52 per thousand surgical cases) was found in the prisoner of war group. This was six times higher than the American (8.0 per thousand), four times higher than the Free French (12.3 per thousand) and seven times greater than the civilian (7.8 per thousand). This was probably due to delay in the initial dressing of the wound and also to the delay between wounding and definitive therapy. Evidence tended to point to the increased fragility and friability of the German clothing and the larger amounts of this clothing found in the wounds.

As has been suggested previously (Bailey [3]) we have shown that wounds of the buttocks were most prone to develop gas gangrene (55.4 per thousand cases), those of the thigh next (37.2 per thousand cases), shoulder (11.2 per thousand cases), upper extremity (10.3 per thousand cases) and leg (9.7 per thousand cases).

Active treatment of gas gangrene infection must begin early to produce maximal beneficial effects. Once clinical gas gangrene has developed, the therapy must center around radical surgery, laying the wound wide open, the lavish use of counterincisions and, if necessary, amputation of the part. In the entire series five upper extremities and seven lower extremities were amputated for this reason.

Surgery alone, however, was not completely efficacious in treating the infection. Sulfonamides, penicillin and gas gangrene antitoxin, together with the use of vigorous supportive measures, were of inestimable value in the saving not only of limbs but also of lives.

From our observations we have felt that the sulfonamide compounds were of little value against the clostridia themselves but had tremendous therapeutic effect against other contaminants of the wound. This is in agreement with many other observers. Hac and Hubert,[2] McKnight, Loewenberg and Wright [2] and others have demonstrated the inefficacy of sulfonamide compounds against the gas gangrene infection in both in vivo and in vitro experiments.

The value of penicillin has been a question for some time. There is no doubt that penicillin alone, or even complemented with gas gangrene antitoxin, is insufficient to inhibit the disease once infection has set in and has begun to spread. In vitro experiments [4] held promise that this drug would be of value in the treatment of clostridial infections. Animal experiments with penicillin have not carried over completely to man, and Keefer, Blake, Marshall, Lockwood and Wood [5] indicate that more clinical observation is needed in human cases before adequate conclusions may be drawn.

Jeffrey,[6] Cutler[7] and Harvey and Meleney[8] were disappointed with the effect of penicillin when used against Cl. sordelli and Cl. welchi. On the other hand, Herrell, Nichols and Heilman,[9] Kepl, Ochsner and Dixon[10] and others are satisfied that this drug is satisfactory in the treatment of the infection. We, from our observations, are heartily in accord with the latter. Penicillin in large doses, both locally, intramuscularly and intravenously, has helped in the reductions of both mortality and morbidity of the disease.

We furthermore are in accord with Herrell[9] and the British investigators[11] that penicillin alone is not efficacious and that it must be combined with the antitoxin and surgical operation. While penicillin may definitely inhibit the growth of the organisms, the neutralizing effect of the antitoxin is essential for the cure of the disease. However, we have found that the preoperative use of the antitoxin is not to be recommended. Moreover, we have been able in most of our cases to determine the amount of antitoxin needed postoperatively by judging the effect on the clinical course of the toxemia.

SUMMARY

1. Ninety-six cases of clinical gas gangrene infection were treated at an evacuation hospital in four months of service in northern France, an incidence of 16.0 per thousand battle casualties.

2. The incidence of gas gangrene was highest in the prisoners of war (62 per thousand battle casualties) and was considerably lower in Americans and Free French (9.9 per thousand and 12.3 per thousand respectively).

3. The development of gas gangrene is influenced by the time interval between the initial wound and the primary first aid dressing; also by the delay in accomplishing definitive surgery.

4. Gas gangrene is most prone to develop in wounds of the buttocks, thighs, shoulder and upper and lower extremities in the order named.

5. Radical, extensive, thorough and early surgery is the most important factor in the prophylactic and therapeutic treatment of gas gangrene.

6. Sulfonamides, both locally and by mouth, have little or no effect on the development of gas gangrene.

7. Penicillin in large doses was found to be an excellent adjunct in the chemotherapeutic treatment of gas gangrene. It is not sufficient in itself to control the infection but, when used in conjunction with surgery and antitoxin, has been of inestimable value.

8. Gas gangrene antitoxin appeared to have little value preoperatively. Its main value is the neutralization of the toxemia postoperatively. Furthermore, little effect against the organisms themselves was noted. The dosage could not be dogmatically determined, since it varied with the degree of toxemia. A minimum of eighteen therapeutic doses is recommended when no sensitivity or other contraindication is found.

9. Eleven patients of the total of 96 died as the direct result of gas gangrene infection, a mortality rate of 11.5 per cent.

THE TREATMENT OF CERTAIN TYPES OF FRACTURES

WITH A V2A STEEL NAIL IN THE MEDULLARY CAVITY (THE KÜNTSCHER METHOD)

B. M. TORDOIR, M.D.
AND
E. J. MOEYS
Surgeon and Fellow of Surgery, Respectively
NYMEGEN, THE NETHERLANDS

Böhler[1] in his book predicted that "advances similar to the Sven Johansson treatment for fractures of the neck of the femur would enable us in the future to treat certain types of fractures of other bones in the same way." His words came true when in 1940 Küntscher[2] introduced his method. His experiments on animals had proved that fractures of the shaft of the long bones had healed very nicely by putting a V2A nail in the medullary cavity through a small opening in the epiphysial end. Since then he has treated many cases with excellent results and in 1944 Böhler published a third volume to his book giving the results in 500 cases.

As the nail finds its fixation in both the epiphysial ends without injuring the articular cartilages (in children great care should be taken to avoid the epiphysial disk) it will be understood that the best type of fracture for this method is the transverse one in the diaphysis. The nail in these cases gives a very exact reduction without chance for displacement. A few days after the operation—which should be done as soon as possible after the accident—the patient is able to walk about and to leave the hospital. In particular to elderly people this means a great advantage as it prevents a stiffening of the joints, atrophy of the muscles, decubitus and hypostatic pneumonia. The exact reduction of the transverse fracture with its frequent great displacement of the fragments and the quick mobilization form the best indication for the use of the Küntscher nail. In the more oblique type of diaphysial fractures only the exact reduction is in some cases already an indication. For compound fractures—if treated within the time limit of six to ten hours—the same indications are of value. Excellent results are also reached in the treatment of pseudarthroses, provided the fibrous tissue is removed and fresh bone surfaces are approximated.

Fig. 1 (patient A, man aged 52).—Closed transverse fracture of the femur.

Küntscher and later his collaborators (Maatz) used nails of different form and sizes in accordance with the type of bone. For the femur they use a straight type of nail and for the tibia and humerus a slightly curved one. Before the operation a very exact x-ray examination should be made of the width of the medullary cavity and the length of the bone. The reduction of the fracture

A more extensive publication on this subject will appear shortly.
From the Surgical Department of the St. Canisius Hospital, Nymegen (in the already liberated part of the Netherlands).

2. Kuntscher, G.: Zentralbl. f. Chir. 67: 1145 (June 22) 1940; 68: 1837 (Nov. 21) 1942.

is done with the help of a special frame under fluoroscopic control, and special attention should be given not only to the exact reduction of both the fractured ends but also to the exact reduction of the axis of the whole bone in regard to the axial fixation of the nail in the spongy substance of the distal epiphysis. For the femur an opening is made in the trochanteric fossa just medial of the greater trochanter with a piercer, and a thin stiff nail is pushed toward the medullary cavity beyond the fracture into the distal fragment. Then the Küntscher nail is slipped over the thin wire, which then will be removed. For the tibia a weak spot just above the tuberosity and in fractures of the humerus both the epiphyses are used.[3]

As will be easily understood, a complete set of instruments and a large collection of nails, an excellent x-ray equipment, reduction frames and an extensive experience are needed if good results are to be obtained. X-ray controls in connection with the formation of callus must be made at regular intervals to determine the date of the removal of the nail. Through a small incision the perforated head of the nail, which all the months needed for consolidation remained outside the bone, is "hooked" with a special instrument, and without any force the nail is easily removed.

Though the method introduced by Kuntscher is an operative one, the extent of the operation is limited to a very small incision at the epiphysial end at the time of the application and the moment of the removal of the nail. Any type of anesthesia which gives complete relaxation of the muscles may be used.

Our own experience with the Kuntscher method is a very good one despite the many great handicaps we had and which were due to war conditions. We had at our disposal only a limited number of nails on the one hand and a very large number of war casualties on the other, who arrived in such numbers in our hospital that, even if we had had a sufficient number of nails, we nevertheless could not have handled them all in the required time limit for the treatment of compound fractures. In addition to these disadvantages we did not have x-ray screens to control reduction during operation, so we decided in some cases to open the fracture and to put the nail in the shaft—in case of a femur fracture in the proximal fragment—and hammered it retrograde in the epiphysis. Subsequently reduction was done and the nail brought in the distal fragment.

Our experience with the Kuntscher method may be divided into two groups: (1) closed fractures and (2) compound fractures.

1. We operated on 21 closed fractures of the femur, 5 of the tibia, 2 of the humerus, 2 of both radius and ulna, 2 of the fibula and 2 of the olecranon. Figures 1 and 2 show ideal types of transverse diaphysial fractures of the femur and humerus. These patients, aged 52 and 13 respectively, left the hospital after fourteen and eighteen days.

That also in the spiral type of fracture the result may be excellent is demonstrated by figures 5 and 6, of a spiral fracture of the femur in a child of 12 years, though a quicker mobilization than normal could not be obtained.

In cases of a fracture at the lower and diaphysial end of both tibia and fibula we put a thin V2A steel wire in the medullary cavity of the fibula, then reduced the very often greatly displaced tibia fragments under fluoroscopic control (in the x-ray department of the hospital) and applied a circular plaster of paris cast. To prevent possible formation of a pseudarthrosis (as might be feared to develop with an "intact" fibula) we had the patient mobilized soon after the operation.

In rare cases of epiphysial fracture the nail may be of great value, as is shown in figures 7 and 3 of a subtrochanteric fracture of the femur with a great displacement of the fragments. Fractures of the olecranon may also be treated with a Kuntscher nail.

Our 10 compound cases had at the time of their arrival in the hospital a complete revision of the wound

Fig 2 Fig 3 Fig 4

Fig 2 (patient A).—Immediately after Küntscher nail has been introduced ideal reduction, axis of the bone restored. Fig 3 (patient C).—Nail introduced ideal reduction of the fracture shown in figure 7. —a splint and sulfanilamide locally as well as generally. In this way we were able to prevent infection of the wound to a large extent. If then, sometimes after weeks, we had a nail at our disposal, we placed it in the medullary cavity and covered the periosteum with muscle but left the wound completely open to enable drainage of the wound secretion. Kuntscher himself never went so far as to use his method in compound fractures secondarily. Probably he did not have to. But we had many cases with a complete fragmentation of the bone by shell or bomb fragments and a very substantial displacement of the bordering shaft fragments. We expected that the nail, besides an ideal

3 Nordmann. Arch. f. klin. Chir. **200**: 71, 1940.

restoration of the axis of the fractured bone, should enable the formation of new bone substance around that part of the nail which bridges the defect, as at least some of the bone splinters might furnish the necessary osteoblasts.

Other advantages might be obtained: easier and less painful handling of the extremity, the possibility of using the joints, the prevention of atrophy and last but not least the decrease of the wound secretions. In some cases traction should be exercised to forestall the shortening of the bone, which happened sometimes when the muscles retracted the distal fragment to the proximal one, in particular in cases in which a certain area had been split up into many small fragments. Though theoretically we considered the possibility of a developing osteomyelitis outside the place of the fracture, we never saw it happen. In this respect we attached great value to the use of sulfanilamide both locally and generally. All the aforementioned objectives were reached in most of our cases. Figure 4 shows a case of compound splinted fracture of the humerus in a girl of 17 in which bony reunion in ideal position was obtained.

Even in late cases of compound fractures the method may prove to be of value.

Ascendency in Medicine.—A distinguished historian recently remarked that few nations which have achieved ascendency in medicine retain that preeminence for more than fifty years. French medicine gained a commanding influence in the Western World during the time of François Magendie; soon after he died, leadership passed largely to Germany; now it has come to England and the United States. Magendie's life coincided with the most critical period of French history: the chaos of the late eighteenth century, the French Revolution and the subsequent rise of democratic government and the appearance of physicians such as Corvisart, Bichat, Laënnec, Louis and Cruveilhier. Then came the rise of scientific medicine associated so intimately with the names of Flourens and LeGallois, but more particularly with the positive leadership of Magendie. —Olmsted, J. M. D.: François Magendie, New York, Schuman's 1944.

THE EFFECT OF PENICILLIN ON HEPARIN TOLERANCE

LAURENCE E. HINES, M.D.
AND
DONALD L. KESSLER, M.D.
CHICAGO

The occurrence of extensive visceral hemorrhages in 2 patients with bacterial endocarditis treated by penicillin suggested this study.

REPORT OF CASES

CASE 1.—Mrs. M. S., white, aged 37, entered St. Joseph Hospital May 5, 1944 because of intermittent chills and fever since November 1943, starting three weeks after the delivery of a normal child; weight loss of 20 pounds (9 Kg.) in six months; sudden onset of right hemiplegia on Jan. 30, 1944, which had improved considerably since its onset; moderate dyspnea, palpitation, and morning headaches. Physical examination showed pallor, emaciation, and evidence of an old right hemiplegia. The lungs were normal. The heart was slightly enlarged. There was a loud blowing systolic murmur over the mitral area. Serial blood cultures taken on admission showed hemolytic streptococci which developed in culture only after seven days. There was a moderate microcytic, hypochromic anemia. The white blood cells numbered 6,700 per cubic millimeter. The urine contained a small number of erythrocytes and leukocytes.

Between May 27 and June 8, 1944, 700,000 units of penicillin was given intramuscularly. Two days after receiving the first injection of penicillin the temperature was normal and there was spectacular symptomatic improvement. However, on June 21 she suddenly developed generalized tonic and clonic convulsions lasting for two hours, followed by contusion. She became comatose on June 23 and died on June 26.

The anatomic findings at necropsy were extensive spontaneous subarachnoid hemorrhage of the base of the brain secondary to a large hemorrhage of the pons, almost healed endocarditis of the mitral valve (hemolytic streptococci, clinical), small recent infarct of the left lung, ancient infarct of the spleen and cystitis of the urinary bladder.

The changes on the mitral valve were mild—only slight toughening—but the changes in the brain were extensive. A thin layer of hemorrhage in the subarachnoid area covered the medulla, pons cerebral peduncles, and portions of the cerebellum and temporal lobes. The pons contained an oval area of hemorrhage 2.5 cm. in diameter, and there was a perforation into the third ventricle. Both lateral ventricles and the third ventricle contained blood clot.

CASE 2.—Mrs. O. B., white, aged 22, five months pregnant, entered St. Joseph Hospital on May 12, 1944, complaining of a profuse vaginal discharge and dysuria for one month, chills, fever and multiple painful swollen joints for six days. The heart, lungs and abdomen were normal. Cervical and urethral smears and cultures showed gonococci. The patient was given a total of 24 Gm. of sulfamerazine in five days and was dis-

From the Departments of Medicine, Northwestern University and St. Joseph Hospital.

charged on May 17, symptom free. One week later at home the patient had a recurrence of her symptoms and again received 20 Gm. of sulfamerazine.

On June 24 the patient entered the hospital complaining of chills, fever, malaise and a weight loss of 17 pounds (7.7 Kg.). Essential physical findings at this time were a seven months pregnancy; daily fever to levels as high as 104 F.; pallor; fine moist rales in both lung bases, moderate enlargement of the heart; loud blowing systolic and diastolic murmurs at the left base, a harsh systolic murmur at the right base and a soft systolic murmur at the apex; and liver enlargement 4 cm. below the costal margin. The spleen was not palpated. There were no petechiae. There was a moderate hypochromic microcytic anemia. The white blood cell count was 17,600 cells per cubic millimeter. The urine contained many erythrocytes and leukocytes but no albumin or sugar Serial blood cultures were negative after twenty-one days

On June 27 the patient, in the seventh month of pregnancy, went into labor and delivered a viable baby. Intramuscular penicillin was then started, and in the next twelve days 1,200,000 units was given. During the first five days 1,100 mg. of heparin also was given. In addition the patient received transfusions

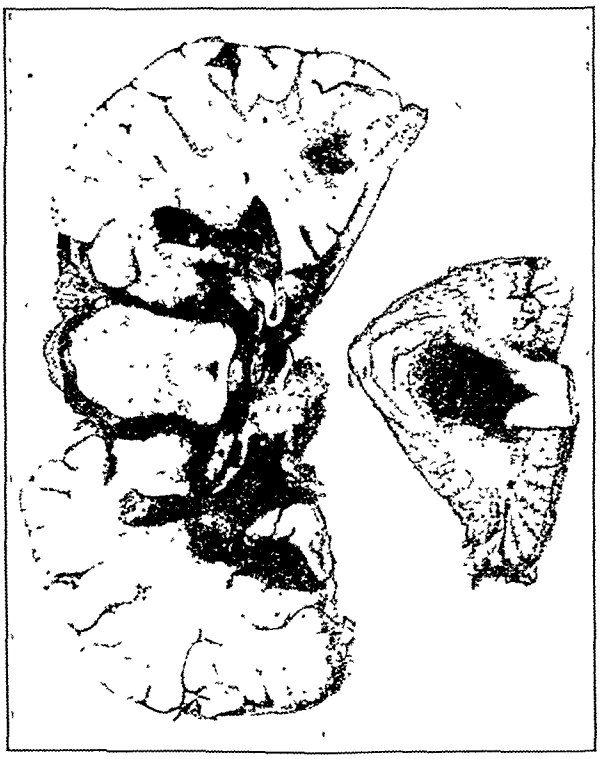

Fig. 1 (case 1).—A thin layer of hemorrhage in the subarachnoid area covers the medulla, pons, cerebral peduncles and portions of the cerebellum and temporal lobes. The pons contains an oval area of hemorrhage 2.5 cm in diameter, with a perforation into the third ventricle. Both lateral ventricles and the third ventricle contain blood clot.

of whole blood. The temperature gradually subsided and reached normal in seven days. However, the patient developed an intractable cough, and there were many coarse rales scattered throughout both lung fields The respiratory rate and pulse rate increased. The abdomen gradually became distended, and on July 7 there was a generalized anasarca. There was no abdominal pain or vomiting The patient developed anuria on July 9 and died on July 10.

The anatomic findings at necropsy were vegetative and ulcerative endocarditis of the aortic and tricuspid valves with erosion and perforation of both valves, acute perforated ulcer of the stomach with extensive hemorrhage into both the lesser and greater peritoneal cavities; extensive petechial hemorrhages of the peritoneum, pericardium, pleurae and serosa of the small intestine; pronounced dilatation of the right atrium; slight dilatation of the left ventricle, right ventricle and left atrium; retained placenta in an enlarged uterus; acute splenic tumor; cloudy swelling of all viscera; chronic passive hyperemia of the liver, and bilateral hypostatic pneumonia.

The greater peritoneal cavity contained air and over 1 liter of partially clotted blood. The lesser peritoneal cavity was also filled with clotted blood. High up on the posterior wall of the stomach was an oval perforation 1 cm. in diameter.

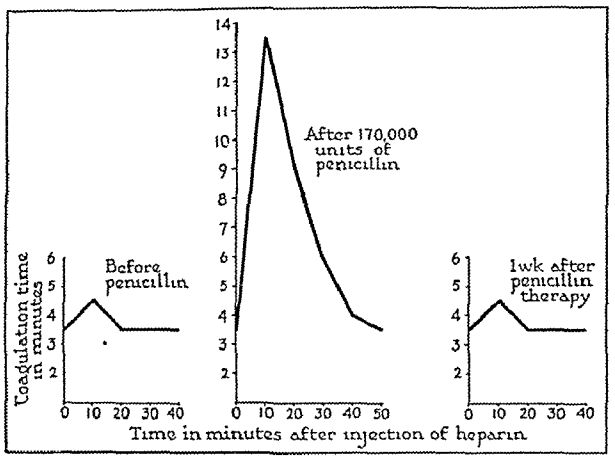

Fig. 2 (Miss S.).—Interlobar empyema.

Adjacent to the perforation there was a small zone of superficial ulceration. The wall at this site was not thickened. The serosa of the small intestine and the mesentery were mottled with large petechial hemorrhages. Similar but less extensive hemorrhages were observed in the pericardium and pleurae.

COMMENT

The 2 patients whose histories are recorded present the following points of similarity: proved bacterial endocarditis, early improvement by penicillin therapy and fatal termination from hemorrhage, 1 by extensive cerebral hemorrhage, the other by widespread, intraperitoneal, mesenteric and pleural hemorrhages. One patient received heparin, while the other did not. Although one might consider the hemorrhage in each patient to be only a manifestation of the sepsis, we felt that there was enough evidence to warrant a study of the effect of penicillin on the clotting mechanism, and particularly to study the effect of penicillin on the reaction of the blood to heparin. This is particularly important, because many clinicians use heparin in con-

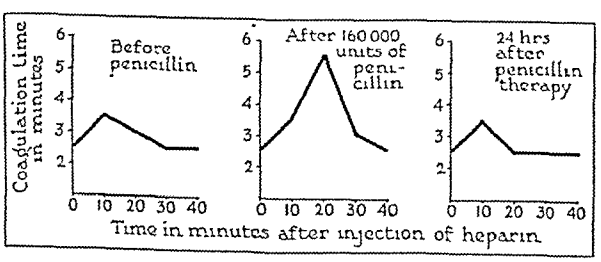

Fig 3 (Mrs. S.).—Hodgkin's disease (control).

junction with penicillin in the treatment of bacterial endocarditis.

Studies were made on a series of patients before penicillin was administered, during the course of penicillin therapy and after the penicillin had been discontinued. These included erythrocyte counts, hemoglobin determinations (Sahli), prothrombin times (Quick), platelet counts (Rees and Ecker) and heparin tolerance

curves (de Takats).[1] In each case the penicillin was administered intramuscularly in doses of 10,000 Oxford units every three hours. The total dosage of penicillin employed varied from 140,000 to 2,500,000 units. In the patients studied there was a variety of disease conditions present. One half of the patients studied had diseases which are not considered suitable for penicillin therapy and therefore served as controls.

Although in the 10 cases studied there were no significant changes in the erythrocyte count, hemoglobin, platelet count or prothrombin time, a definite change was produced in some patients in the heparin tolerance curve. The intravenous injection of 10 mg. of heparin produces a slight increase in the capillary coagulation time, usually maximal in ten to twenty minutes, and increasing the coagulation time to between four and seven minutes. When the maximal coagulation time is less than four minutes the response is classified as a "hyporeactor" and if it is over seven minutes the individual is classed as a "hyperreactor." In 2 patients of our series who had received penicillin (both "normal reactors" before penicillin was administered) a spectacular delay in coagulation occurred after the administration of 10 mg. of heparin, increasing the maximal response to heparin to seven minutes in 1 patient, and to thirteen and one-half minutes in another. In 5 cases mild increases of one to two minutes were noted, but these were not considered sufficiently high to justify any conclusion. In 3 cases no change occurred. Examples of the different types of response are shown in figures 2, 3 and 4.

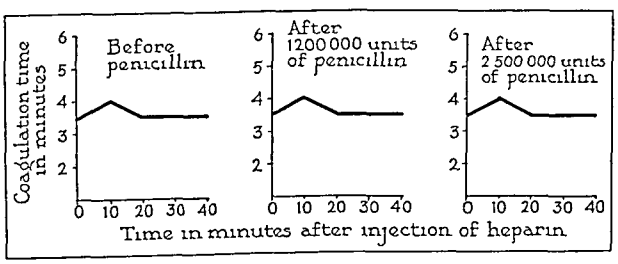

Fig. 4 (Mr. M.).—Subacute bacterial endocarditis

Symptomatic reactions of an allergic type developed in 2 patients. Alarming dyspnea, cyanosis, cough, tachycardia, sweating and weakness were produced by the heparin injected while a course of penicillin was being given. Similar severe reactions from intravenous heparin alone have been recorded by de Takats, and therefore penicillin cannot be incriminated as the offending agent here.

It is well known that some drugs, notably digitalis and the salicylates, change the tolerance to heparin. The patients in this series received only penicillin.

Although sweeping conclusions cannot be drawn from this small series, 2 patients demonstrated a definite increase in blood coagulation time during a course of penicillin, as measured by the heparin tolerance test. Minor changes in 50 per cent suggest a slight tendency of a similar nature in others. This tendency seems to be particularly important in the treatment of patients with bacterial endocarditis if heparin is used as an adjuvant to penicillin. These studies suggest that it is advisable to run heparin tolerance or heparin sensitivity tests as a precautionary measure if heparin and penicillin are to be used at the same time.

SUMMARY

Death from extensive visceral hemorrhages occurred in 2 patients who had received penicillin therapy for bacterial endocarditis, in spite of great symptomatic improvement following the initial doses of the drug, and in spite of almost complete healing of the endocarditis in 1 case. Subsequent studies on 10 patients receiving penicillin showed profound effects on the sensitivity to heparin in 2 patients, no effect on the heparin tolerance curve in 3 patients and slight but inconclusive increase in 5 patients. No change in the hemoglobin, erythrocyte counts, platelet counts or prothrombin times was demonstrated.

INTRA-ARTERIAL INJECTION OF PENICILLIN FOR INFECTIONS OF THE EXTREMITIES

PRELIMINARY REPORT

S. THOMAS GLASSER, M.D.
JOHN HERRLIN JR., M.D.
AND
BORIS POLLOCK, M.D.
NEW YORK

This report includes 24 cases treated for serious infections in the extremities. We present what we believe to be the first series in which penicillin was administered by the intra-arterial route. The excellent results obtained are noteworthy. These findings assume added importance at this time because 70 per cent of war casualties are associated with wounds in the extremities. An even higher percentage of traumatic lesions of the extremities are observed in war industries. Since these injuries are frequently complicated by infection, a preliminary report on the utilization of penicillin by the arterial route would seem to be timely.

HISTORY

The history of intra-arterial therapy dates back to 1914. In this year Goyanes[1] in Spain, Fiolle[2] in France and Heddaus[3] in Germany injected various drugs with more or less doubtful effect. A few years later, following the discovery of mercurochrome, occasional optimistic reports appeared in the literature. Dos Santos[4] and Lamas[5] in Portugal and Leriche,[6] de Fourmestraux[7] and Fredet[8] in France deserve credit for stimulating renewed interest in the intra-arterial method. The arterial route was utilized for the injection of mercurochrome, gentian violet, colloidal silver, acriflavine and other drugs and serums. Luccarelli[9] reported 36 cases in which the local pathologic con-

dition was favorably influenced in every case from the point of view of control of the infection. Many of his cases which ordinarily would have required incision and drainage were cured by only one intra-arterial injection. He observed that, "no doubt, the intra-arterially injected gentian violet causes changes in the local circulation, witnessed by the purple coloration of the parts most seriously injured, as well as sensations of heat followed by relief of pain and a sense of comfort in the affected limb." Recently the sulfonamides have been used with excellent results. In the present war the Russian authors A. and E. Titelbaum,[10] reported their results as "striking" in which 100 to 150 cc. of 0.85 per cent solution of sulfanilamide was used in 15 cases. Other Russian surgeons, especially Martinoff,[11] mention the prophylactic value of mercurochrome and sulfanilamide for extremity wounds during the present war. In these cases débridement of wounds was routine.

PHYSIOLOGIC CONSIDERATIONS

The physiologic basis of the intra-arterial method is directed toward local concentration of the therapeutic agent into the infected tissues. The standard methods of applying antibacterial drugs are oral, intravenous, intramuscular and topical. In addition, penicillin is also being administered intrathecally, intrathoracically and intra-articularly with excellent results, these methods proving the efficacy of direct or local concentration. On the other hand, topical application must be differentiated from what we have termed "direct" or "local" use by virtue of the proved data that the former is effective only superficially. The beneficial effects observed when penicillin is deposited in pleural or synovial cavities is unlike the usual local application on wounded surfaces probably because penetration of the drug takes place more readily in the former method. Herrell, Nichols and Heilman[12] have shown that the greatest blood concentration of penicillin, until now, has been obtained by the intravenous route. However, we have been able to reach higher blood levels by means of the arterial method. It is obvious that any drug introduced by any of the preceding routes except the arterial must necessarily be diluted by the volume of the circulating blood. On the other hand, the intra-arterial method implies a minimal dilution of the medicament whereby a higher concentration than by any other means results in the tissues nourished by the artery utilized for the injection. Furthermore, in the presence of inflammation the capillary permeability increases, thus allowing for greater filtration of the drug, which is deposited in greater concentration in the locus of infection and subsequently is released slowly to the general circulation. The fixation of the drug in the infected area is even more effective if, immediately following an intra-arterial injection, a tourniquet is applied proximally for ten minutes. By the method of stasis the concentration of the drug increases. Dos Santos [4] showed by arteriographic studies that the application of elastic compression retarded the passage of medicaments into the general circulation. He injected sodium iodide into the brachial artery and applied a tourniquet proximally. Fluoroscopy revealed that about fifteen minutes after the injection the shadow was visible; then the vessel gradually lost its opacity, "but the tissue gradually became more accentuated, obviously due to the fixation of sodium iodide in the tissue." Other experiments which illustrated the phenomenon of concentration were those of Leriche [6] and Goyanes,[1] who obtained anesthesia of an extremity following the injection of procaine into the vein and artery respectively only by employing the method of stasis. They failed to obtain anesthesia without the application of the pressure cuff. The toxic effects of procaine and absence of anesthesia were evidenced only in those instances in which the tourniquet was not applied. However, it is also of great importance to know beforehand that the molecular weight, p_H and transfusibility of the drug is physiologically adapted for contact and fixation in the involved tissues. Following intra-arterial injection the vasomotor response, increased warmth of the limb and flushing of the skin are noted. How much of this is due to reactive hyperemia following the release of the tourniquet, and what part of this vasodilatation can be attributed to the action of the drug itself has not been determined. Leriche [6] observed an increased temperature of the limb following injection of the femoral artery not only with procaine but with antibacterial substances. His patients indicated that during the injection a wave of warmth descended along the injected artery. Besides the concentrated and prolonged action of antibacterial substances by the arterial route, this procedure allows for greater mobilization of the immunologic forces of the body against bacterial invasion.

COMPLICATIONS

The employment of drugs approaching isotonic concentration for intra-arterial injection should obviate serious complications. Lami [13] notes that there should be no hesitancy about injection through an artery, since it is less fragile than a vein; because elasticity of the needle puncture in the artery wall closes more rapidly than in a vein. Huet and Bargeton [14] and Wilmoth [15] established by animal experimentation that solutions injected intra-arterially were safest when isotonic and with a p_H near that of the blood, thereby avoiding damage to the intima. In our experience we have never encountered arterial thrombosis. Only few serious complications are recorded in the literature and these apparently due to faulty technic or poor selection of the medicament. Dos Santos [4] mentions occasional arterial and venous spasm in the upper extremity, rarely in the lower extremity. He has eliminated this complication after its occurrence by sympathetic ganglion block with procaine. He has never seen arterial thrombosis resulting from this method. Pain, lasting only a few minutes, was occasionally observed during or shortly after injection. Some of our patients complained of moderate pain during the injection, but this disappeared immediately following deflation of the blood pressure cuff. The literature also mentions hematoma as a complication. In no instance have we had this experience, probably because of attention to technic which will be described in the following paragraph. Leriche [6] has not experienced toxic reactions when using the arterial route for the introduction of mercurochrome which were noted when the intravenous route was employed. In our series of 24 cases reported in this paper, no complications except for occasional moderate transitory pain were found.

CONTRAINDICATIONS

Luccarelli [9] states that the intra-arterial method is contraindicated in hypotension, diabetes, nephritis and arterial incompetence, although he gives no justification for these beliefs. On the contrary, our experience leads us to disagree with this author's views. We have not found any contraindications in the intra-arterial method of utilizing penicillin. Arterial thrombosis as a disease entity might be considered as a possible hazard. We feel that it is of no significance other than that it would not lend itself to the introduction of the drug. Here the method of injecting the vein followed by stasis could be substituted. Furthermore, we have injected the femoral artery in the presence of advanced arteriosclerosis without any side-effects. Locally infected areas or thrombophlebitis may be considered as contraindications.

TECHNIC

We mention precautionary measures to be observed before outlining our technic of intra-arterial injection. We are in agreement with Wilmoth in cautioning against transfixion of the artery with the needle. This may be avoided by entering the artery obliquely. It is not essential that the needle be placed in the direction of the blood stream, as mentioned by many writers. Rhythmic jets of blood into the syringe must be observed before injecting. Our technic of intra-arterial injection is as follows:

We employ a 20 cc. syringe to which a gage 20 needle 2½ inches long is attached. In the lower extremity the injection is made into the femoral artery, piercing the skin in the crease of the groin. The left hand palpates the femoral artery, which is best felt above the inguinal crease, especially in obese persons. The artery is fixed between the index and third fingers of the left hand, and the needle is directed from below upward. Close proximity to the artery is noted when an arterial impulse is transmitted from the point of the needle to the syringe. A bright or light colored pulsating stream of blood appearing in the syringe, which contains 50,000 units of penicillin (10 cc.), indicates that the needle is within the lumen of the artery. In the upper extremity, depending on the location of the infection, the brachial artery is punctured at the elbow or more proximally. The blood pressure cuff, which has been applied proximal to the infected area at the beginning of this procedure, is inflated rapidly immediately following completion of the injection, which has been given at the rate of 1 cc. per second. The pressure in the cuff should be 280 to 300 mm. of mercury and is maintained for ten minutes. In order to avoid the possibility of hematoma formation, digital pressure over the puncture site is applied immediately on withdrawal of the needle.

Depending on the local effects and the systemic response (decrease in pulse rate and temperature), a second, third or even fourth intra-arterial injection may be necessary.

PENICILLIN DOSAGE AND EVALUATION

We have empirically used a dosage of 50,000 units of penicillin per injection in all of our cases. Although the clinical results were beyond expectations, the optimum minimal dosage is still left to be ascertained. In our series of cases reported in this paper we have dissolved 50,000 Oxford units of penicillin in 10 cc. of isotonic solution of sodium chloride. This may be regarded as being ideal for intra-arterial injection, since it is practically isotonic. The p_H of this solution as determined in our laboratories is 7.4 (p_H of blood is 7.3-7.5).

The bacterial flora commonly found in infections of the extremities is usually responsive to penicillin. The question arises how this drug of choice should be utilized to its best advantage. Romansky and Rittman [16] have described a new method for prolonging the action of penicillin by the medium of beeswax in peanut oil given intramuscularly. Fleming and his collaborators [17] in a recent paper mention the use of penicillin either by continuous administration with a low level for an extended period or by an intermittent method of high blood levels of penicillin for short periods. In the latter method the blood level is low before the succeeding injection is given. In most of our cases we found that a lapse of several days between injections did not alter the efficiency of our regimen, provided a careful clinical supervision was practiced, the status of the case being evaluated from day to day. This intermittent injection method was found to be advantageous by Bigger [18] in his experimental studies on the action of penicillin in vitro. He was prompted to conduct this investigation in seeking the cause for the not infrequent failures of penicillin action against staphylococci. He concluded that penicillin is bactericidal for Staphylococcus pyogenes in concentrations from 1/24 to 1 unit per cubic centimeter. In the serums of patients undergoing treatment, the concentrations are more commonly 1/16, 1/8 and 1/4 unit per cubic centimeter, while 1/2 to 1 unit occurs only occasionally. Furthermore, failure to sterilize broth containing Staphylococcus pyogenes is due to the survival of a small number of staphylococci called "persisters." It is believed that persisters are insensitive to penicillin because they are temporarily in a nondividing phase and because penicillin destroys only bacteria which are about to divide. Unlike resistant strains, descendants of persisters are readily destroyed by penicillin. Bigger [18] is of the opinion that there is good clinical evidence that many bacteria other than Streptococcus pyogenes and penicillin sensitive nonhemolytic streptococci also produce the same kind of "persisters." He concludes from his studies with staphylococci that the same might apply to other bacteria and suggests the use of the fractional or intermittent method of sterilization as employed to kill spores in culture mediums. During treatment all cocci in a susceptible phase should be killed by penicillin. During periods of absence of treatment, persisters should begin to divide and thereby become susceptible to penicillin. But, since the persister phase may be of long duration, several alterations of treatment would be required for the complete elimination of staphylococci from the body. Furthermore, it is desirable to maintain 1/2 to 1 unit per cubic centimeter for optimum effect. The wastefulness and impracticability of continuous intramuscular or intravenous injections of penicillin for long periods in the treatment of local infections in the extremities is apparent from the foregoing discussion. For these reasons the intra-arterial introduction of penicillin is ideal. The method is both local and economical. In our experience, one daily injection of 50,000 units of penicillin was sufficient to cope with even the severest infection. We have found concentrations as high as

4.4 units per cubic centimeter of serum in venous blood taken eleven minutes following release of the cuff and 3.6 units in twenty-five minutes.

WAR WOUNDS: SUGGESTED APPLICATION OF INTRA-ARTERIAL METHOD

Our experience with the intra-arterial injection of penicillin, especially in cases of severe infections complicated by diabetes and arteriosclerosis, prompts us to suggest the use of this method for war wounds. We believe that many lives and limbs could be saved by the utilization of the arterial route Experiences of this war have shown that, under the unfavorable or limited conditions near the battle fronts, even with the application of sulfonamide drugs and débridement primary wound closure is a risky procedure. At present the medical corps practices primary closure only for wounds of the head, face and chest, while in extremity wounds débridement without sutures is the accepted procedure. Occasionally secondary closure is performed. Wilson and Threadgill[19] report about 105 cases in which secondary closure of wounds was practiced in order to obtain "better cosmetic results, more rapid general improvement, and the avoidance of the possibility of protracted ulceration of a large cicatrix."

The following scheme of treatment of war wounds is suggested:

1. *Prevention of Infection.*—(*a*) The first intra-arterial injection of penicillin should be given as soon as possible. This simple procedure might be allotted to an advanced medical unit equipped with a sterile 20 cc. syringe, needle and penicillin Wherever possible, débridement should precede the injection.

(*b*) If débridement is deferred, a second intra-arterial injection following this procedure is advisable because the initial injection will not have destroyed the bacteria in the contaminated necrotic tissue which is deprived of its normal blood supply

(*c*) In some cases with minimal contamination and damage of the tissues a primary wound closure followed by intra-arterial injection could tentatively be attempted with or without débridement.

(*d*) Treatment of war wounds of the extremities by intra-arterial penicillin will unquestionably increase the number of cases suitable for early secondary closure and for skin grafting because fewer patients will develop infection. A secondary wound closure should be followed by an additional injection.

2. *Treatment of Infected Wounds of the Extremities.*—(*a*) Infected war wounds of the extremities should receive an intra-arterial injection of penicillin preceded by careful débridement and all pus pockets laid wide open. The number of penicillin injections will depend on the gravity of the case, so that supplementary injections should be given at intervals—every one, two or more days.

REPORT OF CASES

CASE 1.—D. K., a white woman aged 67, was admitted with the diagnosis of impending diabetic gangrene of the left foot complicated by infection. The left foot was much swollen and presented two draining sinuses, one between the first and second toes and another midway down the plantar surface. There were definite signs of cellulitis on the dorsum. The temperature was 101 F. On Sept 16 and 17, 1944 50,000 units of penicillin was given intra-arterially with considerable improvement. On the 19th an incision was made extending from the sinuses between the toes down to the sinus on the plantar surface. This was deepened to the subcutaneous tissues, which were excised and included necrotic and sloughing tendons and muscle, although no actual pus was visible. An additional incision was made on the dorsum of the foot beginning between the great toe and the second toe and extending for a distance of 2 inches. Necrotic tissue was removed. Petrolatum gauze was used for packing and 50,000 units of penicillin given intra-arterially. Bacteriologic examination of the smear showed Staphylococcus aureus, Streptococcus viridans and Escherichia coli. The temperature returned to normal postoperatively and the diabetic status was greatly improved. The wound remained clean and granulating except near the region of the heel on the plantar surface, which showed some necrosis. X-rays revealed osteomyelitis of the third, fourth and fifth metatarsal heads and corresponding toes. On October 2 extensive débridement (fig. 1) was performed including excision of involved bone and necrotic tendons and fascia on the plantar surface followed by 50,000 units of penicillin intra-arterially. This was repeated October 9 and November 7 and 20. The postoperative course was excellent. Healthy granulations appeared and the temperature remained normal. However, with the realization that the foot would be nonfunctioning even if complete healing resulted, it was deemed advisable to amputate below the knee. This operation was performed and followed by 50,000 units of penicillin intra-arterially. Healing occurred by primary union.

This patient was admitted with what is generally agreed on as a definite indication for emergency amputation because of pronounced arteriosclerosis with diabetes complicated by spreading infection on both the dorsum and plantar surfaces of the foot. The usual expected course without amputation would be a rapid spread of the gangrenous process and infection proximally up the leg with systemic reaction. In this case response to intra-arterial penicillin was almost immediate: relief of pain, return of temperature to normal and definite improvement in the diabetic status. Because of inadequate débridement and drainage (this being our first case) a second débridement was necessary before complete control was obtained. Unfortunately the gangrenous process had already destroyed a great portion of the foot, thereby leaving a limb which would be unsuitable for prosthesis. The amputation below the knee was elective. Primary healing of the sutured stump in the presence of infection is definitely attributed to the use of penicillin. This case demonstrated to us the absolute necessity for thorough débridement and drainage in the presence of necrosis and encapsulated pus, since it is agreed that penicillin will not act in such mediums.

FIG. 1.—Debridement in case 1.

CASE 2.—J. V., a woman aged 65, a Puerto Rican with diabetic arteriosclerotic gangrene of the second, third, fourth and fifth toes with osteomyelitis of the heads of the third, fourth and fifth metatarsal bones (fig. 2), had a purulent discharge and inguinal adenopathy; the temperature was 100 F. Smear showed Staphylococcus aureus. Penicillin 50,000 units was administered intra-arterially, repeated two days later with

19 Wilson, H., and Threadgill, F. D Secondary Suture of War Wounds, Bull. U. S. Army M. Dept., 1944, no. 82, p. 77.

extensive débridement, including amputation of the second to fifth toes and the corresponding metatarsal heads with excision of soft tissues. A third penicillin injection was given six days later. The wound immediately became clean and started to granulate within a few days.

Excellent results were obtained in a diabetic patient with suppurative gangrene. This type of case would

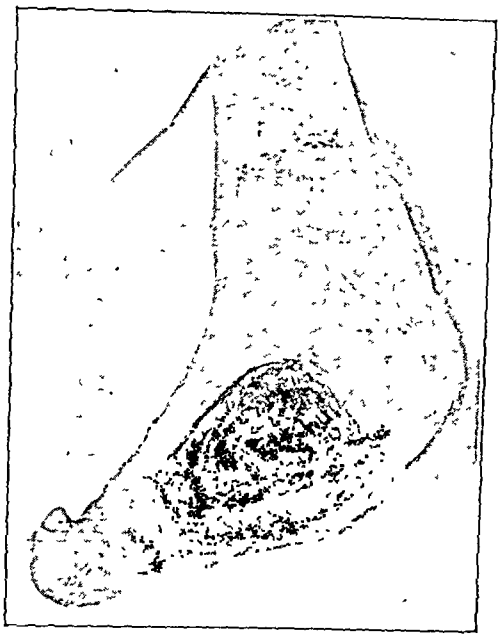

Fig. 2.—Appearance of foot in case 2

ordinarily require emergency amputation through the thigh.

Case 3.—A. S., a white woman aged 41, was in diabetic coma. There was moist gangrene of the left fourth toe with extension of infection into the plantar spaces. Emergency care was given for the coma. Intra-arterial penicillin 50,000 units on two consecutive days resulted in decided improvement. On the fourth day the injection was repeated and the involved toe was amputated, with débridement on the plantar surface. A smear showed Staphylococcus aureus and Streptococcus viridans. The postoperative course was good, but impaired circulation of the fifth toe required additional amputation, including the metatarsal head (fig. 3). Rapid recovery with complete diabetic control resulted. The wound filled in with scar tissue and the patient was able to walk.

In this case diabetic coma with spreading infection of the foot and gangrene of the toe was completely controlled by débridement and intra-arterial penicillin, resulting in a foot suitable for ambulation.

Case 4.—F. H., a white woman aged 56, had diabetic arteriosclerotic gangrene of the left foot including the second, third, fourth and fifth toes; osteomyelitis; cellulitis, and lymphangitis of the dorsum. Three doses of intra-arterial penicillin (50,000 units) were given, the first on the day of admission, the second on the following day when débridement of the left foot with amputation of the second and third toes extending into the intermetacarpal spaces was performed, and the third four days later. A smear showed Staphylococcus aureus. Complete control of the diabetic ketosis with granulation followed. The history revealed that sulfonamide drugs had been taken without avail before admission to the hospital.

In this case serious infection in the foot of a diabetic patient associated with gangrene of the toes responded rapidly to arterial penicillin therapy.

Case 5.—T. H., a Negro man aged 32, was suffering from a human bite on the dorsal surface of the left middle finger of five days' duration. The finger was diffusely swollen and accompanied by slight pain at the onset, which became progressively worse and on admission presented lymphangitis and axillary lymphadenitis associated with a temperature of 101.4 F. Intra-arterial penicillin 50,000 units was given, and drainage with excision of a small amount of slough was performed. The temperature was normal on the following day. Penicillin was repeated in forty-eight hours. The wound remained clean and the patient was discharged.

The usual difficulties encountered in human bites are due to the mixture of organisms in this type of wound. Ordinarily response to treatment is refractory, but with intra-arterial penicillin complete control resulted.

Case 6.—N. W., a Negro woman aged 63, had early diabetic gangrene of the second and fourth toes of the left foot. There were infected ulcers on the second, third, fourth and fifth toes, with osteomyelitis of the phalanges, cellulitis spreading into the plantar spaces, advanced arteriosclerosis and pronounced diabetes. Intra-arterial penicillin 50,000 units was given and disarticulation of the second to fifth toes performed; an elliptic incision included most of the ball of the foot, and the underlying soft tissues were excised. A smear showed Staphylococcus aureus and Escherichia coli. Penicillin was repeated on the second, fourth and tenth days. The postoperative course was excellent and granulations appeared within five days, filling in the wound completely within ten days.

This is similar to the first case except that a more complete removal of necrotic tissues at the onset proved more efficient.

Case 7.—M. N., a white woman aged 55, had a perforating ulcer on the plantar surface of the left foot, diabetes, persistent pain for the previous seven months, a moderately purulent

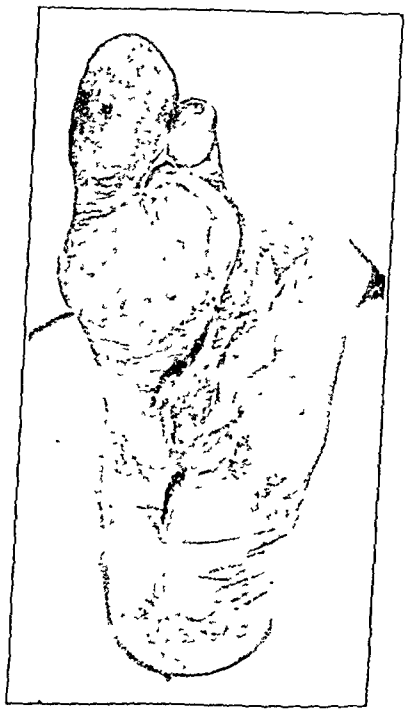

Fig. 3.—Foot in case 3 after amputations

discharge, the margins being covered by hard callus, and moderate arteriosclerosis. Excision of the ulcer and surrounding callus with intra-arterial penicillin 50,000 units was performed. The injection was repeated two days later. Infection was completely controlled and granulations were evidenced within one week. The patient was discharged completely healed two weeks later.

In the presence of arteriosclerosis with diabetes, an ulcer of the mal perforans type is nearly always refractive to treatment. The response to intra-arterial penicillin was exceptionally good.

CASE 8.—D. F., a white woman aged 65, with arteriosclerosis and an infected gangrenous ulcer on the second toe of the right foot with lymphangitis extending on the dorsum, complained of persistent pain. Intra-arterial penicillin 50,000 units was injected and repeated on the third day. Infection was completely controlled, leaving a clean ulcer. Pain was greatly relieved following the first injection.

This case is one of advanced arteriosclerosis complicated by lymphangitis. The danger of progressive moist gangrene in this type of case is recognized. To get results within twenty-four hours is extraordinary.

CASE 9.—E. G., a white woman aged 43, suffered from very large painful infected varicose ulcers on the left leg. A bilateral saphenous vein ligation had been performed five weeks before admission. Intra-arterial penicillin 50,000 units was given and repeated on the third day. Pain was completely relieved within twenty-four hours following the first injection. The ulcer appeared clean on the fourth day.

In spite of bed rest and recent vein ligation, infection of the varicose ulcer persisted until penicillin was given. The organisms found on initial smear were Staphylococcus aureus and streptococci.

CASE 10.—C. P., a Negro woman aged 27, with chronic gonorrheal pelvic inflammatory disease had tenosynovitis of the index finger with much swelling for the past five days, probably of gonococcic origin. Brachial intra-arterial penicillin 50,000 units was given and repeated in forty-eight hours. Immediate improvement was noted, with almost complete subsidence of pain. The patient was discharged two weeks later, completely cured, without limitation of movement of the finger.

This case of probable gonorrheal tenosynovitis readily responded to intra-arterial penicillin without surgical treatment.

CASE 11.—M. G., a white woman aged 56, whose left leg had been amputated through the thigh one month before admission, had diabetic arteriosclerotic gangrene, with infection of the right big toe. Intra-arterial penicillin 50,000 units and amputation of the big toe with the head of the metatarsal was performed and the injection repeated forty-eight hours later (fig. 4). The patient was discharged completely healed three weeks later. The original smear showed Staphylococcus aureus, Escherichia coli and Streptococcus viridans.

This case presents rapid healing, immediate clearing up of infection and rapid epithelization in a case of arteriosclerosis and diabetes complicated by infection.

CASE 12.—Z. A., a white man aged 57, had diabetic arteriosclerosis with cellulitis and lymphangitis on the dorsum of the right foot with much edema. Intra-arterial penicillin 50,000 units was given on admission and resulted in localization of the infection within twenty-four hours. The second injection with incision and drainage was performed forty-eight hours later and resulted in a clean healing wound. The smear showed Staphylococcus aureus.

The dreaded complication of infection in diabetic arteriosclerosis was completely localized in twenty-four hours and cleared up on the third day following a second dose of penicillin.

CASE 13.—D. F., a white man aged 68, had arteriosclerotic gangrene of the right middle toe with localized infection. Intra-arterial penicillin 50,000 units was administered and amputation of the toe was performed. Postoperatively the wound remained clean and granulated.

One injection of penicillin intra-arterially served to keep the wound clean and allowed granulation in spite of advanced arteriosclerosis.

CASE 14.—I. N., a white woman aged 68, had diabetic arteriosclerosis, with gangrene of all the toes of the right foot and moist gangrene of the entire plantar surface and distal part of the dorsum. The involved area was completely debrided and intra-arterial penicillin 50,000 units was given. The injection was repeated for the next four consecutive days. A smear showed gram positive cocci and diplococci and gram positive bacilli. The diabetic status was completely controlled within twenty-four hours. Insulin was not required and the temperature returned to normal. The patient was discharged with a healthy granulating wound.

FIG. 4.—Foot in case 11 after amputation of toe.

The use of penicillin intra-arterially apparently assumes complete control of infection, so that surgical local procedures may be performed which would ordinarily be contraindicated.

CASE 15.—M. J., a white man aged 75, had moist gangrene of the left foot, arteriosclerosis, lymphangitis extending half way up the leg, a temperature of 102° F. and generalized toxicity. A low thigh amputation was performed and the stump was closed without drainage immediately followed by intra-arterial penicillin 50,000 units, which was repeated daily for three injections. The stump healed in one week by primary union.

This case presents the extraordinary result of healing by primary union in an amputation stump closed without drainage in the presence of lymphangitis.

CASE 16.—M. D., a white man aged 52 with diabetes, presented arteriosclerosis, diabetic polyneuritis, hypertension and gangrene of the fourth right toe with spreading cellulitis extending to the dorsum of the foot. His temperature was 103.2 F. The involved toe was amputated and intra-arterial penicillin 50,000 units was given. The temperature subsided within twenty-four hours and penicillin was repeated the following day. However, in spite of the absence of infection the gangrene spread because of arterial insufficiency. The patient refused amputation. Three weeks later in the presence of advanced gangrene and spreading lymphangitis extending up the leg a low thigh amputation was performed with primary closure and resulted in healing by primary union.

In spite of pronounced infection and lymphangitis, primary closure of the stump is possible with the aid of intra-arterial penicillin.

CASE 17.—B. S., a white man aged 70, had necrotic ulcers of the right foot, arteriosclerosis, diabetes and infection. Intra-arterial penicillin 50,000 units was given and repeated four days later. Improvement was prompt and granulations appeared at the ulcer sites within one week. A smear originally showed Staphylococcus aureus.

Acute necrosis and ulceration in the presence of arterial insufficiency complicated by diabetes in a patient 70 years of age is always regarded with alarm. Penicillin prevented extension of infection and we are impressed by the rate of healing which, although delayed by arteriosclerosis, is nevertheless far more rapid than we have ever observed under any other method of treatment.

CASE 18.—P. B., a white man aged 74, was obese and had diabetic arteriosclerotic gangrene of the second toe and heel with infection. Intra-arterial penicillin 50,000 units was given and repeated four days later, resulting in complete control of the infection.

This is another example in which infection was completely controlled in the presence of pronounced arterial incompetence in a diabetic patient.

CASE 19.—N. Y., a white man aged 43, was suffering from dorsal subaponeurotic space infection of the left hand with lymphangitis and pronounced edema. Penicillin 50,000 units was injected into the brachial artery, and incision and drainage were performed. The smear showed Streptococcus viridans and aerobic and anaerobic gram positive diplococci in chains. Injections were repeated on the second and fourth days. Postoperatively the infection subsided completely within twenty-four hours.

The efficacy of intra-arterial penicillin is shown in a case of serious hand infection due to a mixture of virulent bacteria.

CASE 20.—J. O., a white man aged 42, had tenosynovitis of the index finger of the left hand with cellulitis. A bilateral incision followed by intrabrachial injection of penicillin 50,000 units was performed. A smear showed Staphylococcus aureus. The injection was repeated in twenty-four and seventy-two hours with complete control of the infection.

Rapid subsidence of infection in a case of tenosynovitis was obtained with the use of penicillin by the intra-arterial method.

CASE 21.—M. A., a Negro woman aged 39, had ulnar and radial bursitis of the right hand; her temperature was 102.2 F. Two injections of penicillin 50,000 units were given into the brachial artery within forty-eight hours. The swelling on the dorsum and the pain and limitation of movement of the fingers cleared up after three days without surgery.

In the presence of a serious infection without suppuration or necrosis, intra-arterial penicillin will control the infection and result in a cure without surgery.

CASE 22.—C. S., a white woman aged 47 with diabetes, arteriosclerosis and gas infection of the great and second toes extending into the plantar spaces, was given intra-arterial penicillin 50,000 units, and incision and drainage were performed. The injection was repeated on the second and fourth days. The smear showed aerobic Staphylococcus aureus, Escherichia coli and anaerobic Staphylococcus aureus. Complete control of the infection was evident within forty-eight hours.

A severe mixed infection with gas formers in the presence of arteriosclerosis and diabetes was readily controlled by the intra-arterial method.

CASE 23.—F. S., a white woman aged 65 with diabetes, arteriosclerosis and cellulitis of the dorsum of the right foot, was given one intra-arterial injection of penicillin 50,000 units, with complete control of the infection.

This case is another example of the excellent response to the intra-arterial method under adverse conditions.

CASE 24.—J. H., a white man aged 76, had an infected hematoma of the middle of the left leg with cellulitis, lymphangitis and inguinal adenitis. Intra-arterial penicillin 50,000 units was given. The following morning drainage was spontaneous. The injection was repeated and the infection completely controlled.

Intra-arterial penicillin assumed complete control of an infected hematoma despite the presence of suppuration. This result is only partly due to the spontaneous drainage.

COMMENT

These 24 case reports illustrate the excellent results obtained with the use of intra-arterial penicillin, especially in the severe intractable types of infection. Emphasis is placed on infection occurring in extremities as a complication of arteriosclerosis with or without diabetes. It is generally agreed that in cases of arterial insufficiency the primary objects in treatment are, first, to improve the collateral circulation and, second, to prevent infection, which in the greater percentage of cases is the precursor of moist gangrene. Tissues with poor blood supply are exceedingly vulnerable to infection. As previously mentioned, the intra-arterial method with stasis resulted in favorable vasomotor reactions when the circulation was not greatly impaired. Whether or not this side effect is attributable to reactive hyperemia is to be determined. Another noteworthy observation which deserves attention is that, in the absence of suppuration or necrosis, a single injection usually suffices for definite improvement or cure. It may be argued that the usual intermittent intramuscular injection of penicillin might also give good results. But certainly one can predict favorable results without reservation when the intra-arterial route is utilized because local concentration is most efficacious. The relief of pain is another outstanding result. Many patients have definitely been saved from major amputation. Again, a lower amputation site has become permissible because infection can be controlled. Primary closure of all amputation stumps in the presence of infection is now practiced in our surgical service. The value of this innovation is obvious. It is expected that subsequent studies will reveal a wider scope for the application of the method of intra-arterial injection with penicillin and stasis because of the high local concentration of the drug used by the intermittent method. Included in our technic is débridement of necrotic and devitalized tissues or incision and drainage in the presence of suppuration, performed prior to arterial injection. This is important because pus cavities and dead tissue are not reached by this or any other method of administering antibactericidal drugs. We realize that this preliminary report is incomplete from the standpoint of thorough investigation and research. Determinations of local tissue and systemic circulation concentrations of penicillin should be made in every case. These data are contemplated for subsequent publication.

SUMMARY

1. Twenty-four cases of severe infections of the extremities were successfully treated by the intra-arterial injection of penicillin.

2. The intra-arterial route allows for greater local concentration of penicillin.

3. Relief of pain is observed.

4. Amputation may be obviated in many cases.

5. Lower amputation sites are more frequently permissible.

6. Primary closure of the stump in the presence of infection is successful.

7. One injection may effect a cure in the presence of inflammation without suppuration or necrosis.

8. The method is economical and rapid in its effect.

Clinical Notes, Suggestions and New Instruments

PRELIMINARY OBSERVATIONS OF THE GASTRIC MUCOSA IN PATIENTS WITH INFECTIOUS HEPATITIS

CAPTAIN WILLIAM A. KNIGHT AND
LIEUTENANT ROBERT C. COGSWELL
MEDICAL CORPS, ARMY OF THE UNITED STATES

In view of the prominence of anorexia, nausea, vomiting and upper abdominal pain in the clinical picture of infectious hepatitis, and because of the paucity of information concerning the pathology of this disease, it was deemed advisable to make observations with the gastroscope to determine whether abnormalities might be found which would throw light on the pathogenesis, symptomatology and pathology of this condition. Patients with infectious hepatitis were therefore examined with the aid of the Schindler flexible gastroscope on the day following admission, except in 1 instance as noted. This report concerns 9 patients whose gastrointestinal symptoms were limited to their present illness. The clinical picture and laboratory findings of these patients were in complete accord with the diagnosis of infectious hepatitis. In every case the history indicated that the disease had been naturally transmitted and was not related to any preceding parenteral injection.

In 7 of the patients examined, the appearance of the mucosa was found to deviate from the normal, and in 2 no abnormality was noted. One of the 2 with normally appearing mucosa had noticed jaundice four days prior to admission, and the other had yellow scleras one month before coming to the hospital. Of the 7 patients whose mucosa was considered to be abnormal in appearance, the clinical course or picture of 1 patient was different from that noted in the other 6. This patient was admitted with epigastric pain, nausea, belching, sour eructations, anorexia and constipation, present to a moderate degree for approximately two weeks before admission and was examined twenty-five days after admission while free from icterus. The examination revealed findings which are generally interpreted as indicating superficial gastritis, i. e. bright, velvety appearing mucosa, with hyperemia, edema, increased highlights and adherent mucus involving the antral and distal fundic portions of the stomach. There were no ulcerations visible. He was discharged from the hospital and readmitted approximately two weeks later with a history that jaundice appeared the day of discharge and seven days after the first gastroscopy. He was reexamined on two occasions during the second admission while he was actually icteric, and a normal appearing gastric mucosa was observed. The remaining 6 patients were all examined with the gastroscope for the first time between four and nine days after the onset of clinical icterus.

In those cases in which deviations from the normal appearance of the gastric mucosa were observed, the area involved was always the antral portion of the stomach, and in some instances the abnormal appearing area extended into the fundus. The findings which have impressed us as being most distinctly abnormal gave the appearance through the gastroscope of being almost identical with small aphthous ulcers commonly seen in the mouth. Five patients in this series were observed to have these ulcerations. The lesions were small, apparently 2 to 5 mm. in diameter, shallow, ovoid or round, with a dirty white base, and in some instances were surrounded by a narrow red areola. They were found in the antrum and on the angularis and varied in number in a given patient from one to four. In 2 patients flakes of mucus were observed adherent to the mucosa of the antral region. Hyperemia and mucosal texture characteristic of superficial gastritis and the ulcerations coexisted in 4 of the aforementioned cases. In none of these patients was peristalsis apparently impaired.

Further study is essential before any conclusions can be formulated with regard to the relationship between the findings in the gastric mucosa which we have noted and infectious hepatitis. The lesion, in our opinion, may ultimately prove to be due to localization of a virus infection and may be either early or late manifestations of the disease or to be secondary to some physiologic disturbance resulting from infection with the virus of infectious hepatitis. On the other hand, the lesion may prove to have only an accidental relationship to infectious hepatitis and will not be found with regularity in cases of this disorder which are examined in the future.

Further cases are to be studied, and a more comprehensive report will be submitted subsequently.

From the Regional Hospital, Fort Benning, Georgia.

THE TETRALOGY OF FALLOT

REPORT OF AN UNUSUAL CASE

EDWARD W. MISKALL, M.D., EAST LIVERPOOL, OHIO

The tetralogy of Fallot,[1] consisting of pulmonary stenosis, right ventricular hypertrophy, interventricular septal defect and dextroposition of the aorta, is the most common combination of congenital cardiac defects attended by cyanosis.

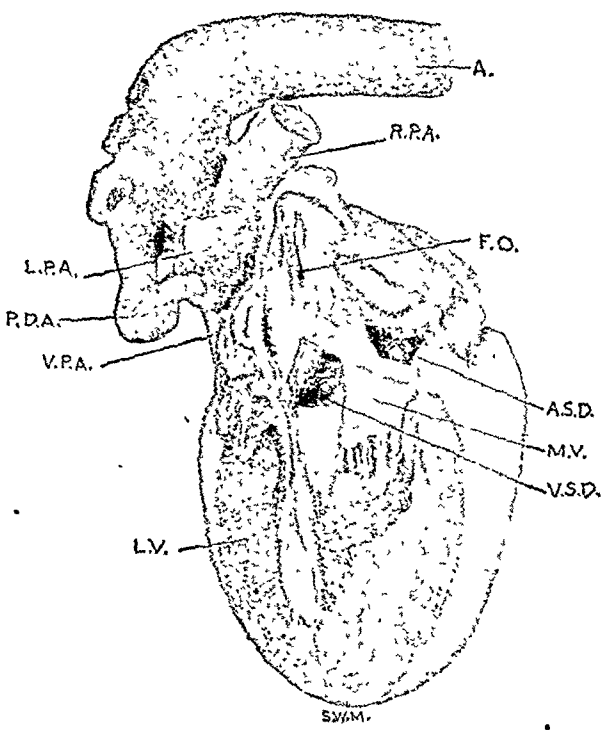

Fig. 1.—Appearance of the heart in the case presented. Part of the wall of the left auricle and left ventricle has been removed. The mitral valve has been divided longitudinally and the anterior flap reflected to expose the interventricular septal defect. *A*, aorta; *A. S. D.*, auricular septal defect; *F. O.*, foramen ovale; *L. P. A.*, left pulmonary artery; *L. V.*, left ventricle; *M. V.*, mitral valve; *P. D. A.*, patent ductus arteriosus; *R. P. A.*, right pulmonary artery; *V. P. A.*, vestigial pulmonary artery; *V. S. D.*, ventricular septal defect.

This case is presented because it had, *in addition* to the classic features of the tetralogy, an interauricular septal defect, a functional foramen ovale and a widely patent ductus arteriosus. The coronary venous sinus was received by the left auricle. There was no innominate artery. The right subclavian and the right common carotid arteries arose directly from the aortic arch.

REPORT OF CASE

B. A. P., a white girl aged 2½ years, seen July 23, 1944, had been cyanotic since birth. Clubbing of the fingers and toes was first noted at the end of the first year. Growth and development had been retarded. The birth weight was 7 pounds

1. Fallot, A.: Contribution a l'anatomie pathologique de la maladie bleue (cyanose cardiaque), Marseille med. **25**: 77, 138, 207, 270, 341 and 403, 1888.

11 ounces (3,487 Gm.). Fretfulness and dyspnea had been present since birth. There had been no acute infections, but there had been sudden attacks of increased dyspnea and cyanosis. These attacks came on without apparent cause at varying intervals. They lasted fifteen minutes to an hour and subsided spontaneously. There were no convulsions or syncope.

Physical examination showed considerable generalized cyanosis, with clubbing of the fingers and toes. A loud coarse systolic murmur was heard over the precordium, maximal at the base of the heart. A soft high-pitched early diastolic murmur was heard over the same area, but it did not fill diastole. No x-ray examination of the chest could be secured. An electrocardiogram showed extreme right axis deviation. Neither the liver nor the spleen was palpable.

The attacks of dyspnea increased in frequency and severity. The death of the patient occurred Oct. 12, 1944 in a particularly severe seizure that came on during a relatively mild upper respiratory infection.

The autopsy was limited to the chest. The lungs were moderately congested. The heart, which was globular, weighed 88 Gm. with the aortic arch attached (normal weight 45 to 55 Gm.). It contained two large auricles and two hypertrophied ventricles. A short fibrous cord, the vestigial pulmonary artery, located just to the left of the base of the aorta

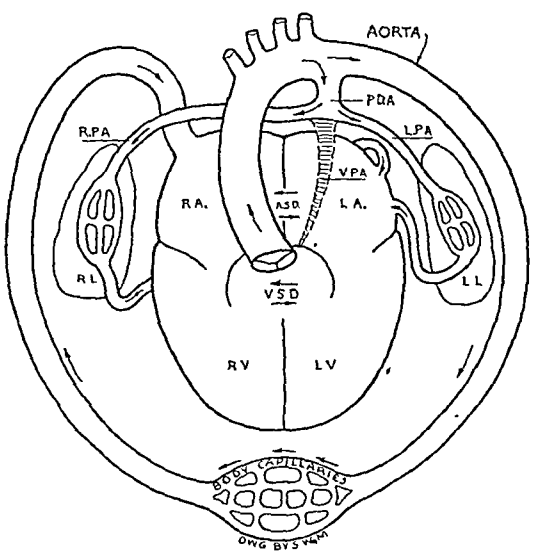

Fig 2.—Diagrammatic representation of the circulation in the case presented. The right common carotid and right subclavian arteries are shown arising directly from the aortic arch. *A. S. D.*, auricular septal defect; *L. P. A.*, left pulmonary artery; *P. D. A.*, patent ductus arteriosus, *R. P. A.*, right pulmonary artery; *V. S. D.*, ventricular septal defect; *V. P. A.*, vestigial pulmonary artery. The shading here indicates the complete impermeability of the vestigial pulmonary artery proximal to the patent ductus. Arrows indicate the direction of flow. Modified after M. E. Abbott and W. T. Dawson (The Clinical Classification of Congenital Cardiac Disease, Internat. Clin. **4**: 156-188 [Dec.] 1924).

(fig. 1), was proximally impermeable but expanded distally to meet the widely patent ductus arteriosus. From the latter, the right and left pulmonary artery branches arose. The right auricle received the superior and inferior venae cavae. The left auricle received the pulmonary veins and the coronary venous sinus. There was a rather large (and probably functional) patent foramen ovale. Posteroinferior to the foramen ovale was an interauricular septal defect 1 cm. in diameter. The auriculoventricular valves were normal. There was a large interventricular septal defect in the membranous portion of the septum which measured 9 to 10 mm. across. The aorta was dextroposed, overriding the defect, so that two thirds or more of the aortic cross section was on the right ventricular side and one third or less on the left ventricular side. The aortic cusps were normal. The coronary arteries were normal and arose in the usual location. The left and right ventricular walls each averaged 10 mm. in thickness. In the upper anterior aspect of the right ventricular wall was a roughly funnel-shaped cavity with its apex pointing to the left and upward. It was 12 mm. in length and 5 to 6 mm. in diameter at its ventricular orifice. This was apparently the vestigial pulmonary infundibulum.

COMMENT

Although this classic tetrad of congenital cardiac defects bears the name of Fallot,[1] who first completely analyzed and recognized it as a clinical entity in 1888, it had first been described by Sandifort[2] in 1777. Hope[3] (1842) also described several cases.

Congenital pulmonary stenosis may follow on a fetal endomyocarditis or it may result from developmental defects. White[4] is of the opinion that the pulmonary valve and infundibulum show evidence of fetal endocarditis more frequently than other parts of the heart because the chief burden of the fetal circulatory effort is theirs. If this occurs late, i. e. after the septums have closed, it may be the sole defect; more often, however, other defects are present, particularly those of the interventricular septum. In Abbott's[5] 1,000 cases of congenital heart disease there were 150 cases of pulmonary stenosis or atresia of the pulmonary infundibulum or valve, 35 cases of aortic or subaortic stenosis or atresia, 19 cases of tricuspid stenosis or atresia and 11 cases of mitral stenosis or atresia.

The developmental type of pulmonary stenosis results, according to Harris and Farber,[6] from delayed involution of the bulbus cordis and from failure of the interventricular septum to close completely. The aorta is frequently dextroposed in these cases, so that it overrides the septal defect and thus receives blood from both ventricles. Furthermore, disturbances in the normal process of torsion may produce the most bizarre anomalies.

Failure of a physiologic mechanism, rather than an embryologic malformation, is given by Kennedy and Clark[7] as the explanation of isolated patency of the ductus arteriosus. However, in this case the patent ductus arteriosus is obviously a compensatory mechanism for the much more serious tetralogy of Fallot.

The patent foramen ovale, while of sufficient size to be functional, was doubtless unimportant as compared to the large auricular septal defect (primitive ostium primum) located posteroinferior to the foramen ovale. In Abbott's[5] series of 1,000 congenital cardiovascular defects there were 36 interauricular septal defects due to persistence of the ostium primum. Eighteen of them complicated other defects, as in the case presented herewith. This type of defect adds to the work of the right auricle and ventricle by pouring an extra volume of blood into the right auricle through the septal defect. This direction of flow from left to right, Uhley[8] ascribes to the effect of gravity, since, as he points out, the right auricle lies below the left, the septum lying horizontally.

The altered cardiodynamics are shown in figure 2. The patent ductus arteriosus provides that some of the blood from the aorta reaches the right and left pulmonary arteries. The extra work imposed on the right side of the heart by the increased blood volume can be appreciated. The right auricle receives blood from the venae cavae and from the left auricle through the interauricular septal defect. The right ventricle must pump the blood it receives from the right auricle against the extra head of pressure that is present in the pulmonary circuit as the result of the patent ductus. The latter, however, may not be as great as is ordinarily present because of the already inadequate amount of pulmonary blood.

Little Building.

COUNCIL ON PHARMACY AND CHEMISTRY

SECRETARY'S INTRODUCTION

For many years the Council on Pharmacy and Chemistry has considered claims for therapeutic usefulness offered on behalf of drugs sold to the medical profession and the general population for the prevention and treatment of infections of the feet. Frequently there was lacking adequate scientific evidence to support the claims. Almost equally lacking, unfortunately, were adequate standards for judging the actual comparative merits of such preparations. At its October 1942 meeting the Council proposed that several authorities in this field be invited to prepare a report on the status of fungicidal agents and offer criteria to aid in the evaluation of such preparations. The Council already has published criteria concerning antibacterial compounds (THE JOURNAL, *Feb. 20, 1943, p. 593). Dr. Fred D. Weidman, Dr. Chester W. Emmons, Dr. Joseph G. Hopkins and Dr. George M. Lewis accepted the Council's invitation and for the past two years have been carrying on investigations, the results of which are incorporated in the following report. The Council wishes to express its appreciation for the assistance provided by these investigators and has adopted their report for publication. This report is intended for all who are interested in the problem of treatment of infections of the feet and especially for medical practitioners, industrial surgeons and manufacturers interested in submitting preparations to the Council for inclusion in New and Nonofficial Remedies.*

AUSTIN SMITH, M.D., *Secretary.*

THE WAR AND DERMATOPHYTOSIS

WITH SPECIAL REFERENCE TO TREATMENT AND FUNGICIDE TESTING

FRED D. WEIDMAN, M.D.
Professor of Dermatologic Research, University of Pennsylvania School of Medicine
PHILADELPHIA

CHESTER W. EMMONS, PH.D.
Principal Mycologist, U. S. P. H. S., National Institute of Health
BETHESDA, MD.

JOSEPH G. HOPKINS, M.D.
Professor of Dermatology, Columbia University College of Physicians and Surgeons

AND

GEORGE M. LEWIS, M.D.
Associate Professor of Clinical Medicine (Dermatology), Cornell University Medical School
NEW YORK

When it appeared inevitable that the United States would be drawn into the European conflict, fresh significance at once accrued to dermatophytosis. War, marching soldiers and their feet are inseparable problems. True, dermatophytosis had already achieved a real position in the medical sun. A ubiquitous annoyance in all strata of society, it occasionally became incapacitating. Notable advance had been made in studies of its pathogenesis, and the principles of treatment, at least, had become crystallized. However, both the general public and the medical profession appeared to be content with the more or less desultory course of events in the study of dermatophytosis, as long as it did not lead to important general constitutional sequelae and remained essentially a disorder of our lowly toes and feet. Indeed, it was the secondary dermatophytids of the hands that aroused most concern; industrial compensation suits often hinged around the question of dermatophytosis or no dermatophytosis.

Following the discovery that no less than 8 per cent of all hospital admissions in the Army and Navy were for cutaneous disease and that dermatophytosis ranked second on the list, certain government agencies as well as the Council on Pharmacy and Chemistry of the American Medical Association supplied funds and facilities whereby its problems could be inquired into more accurately. Among other things this involved a reconsideration of the pathogenesis. To what extent are the predisposing causes of importance, and to what extent are the fungi the exciting agents? Is the reappearance of the disease, once it has cleared up, a recurrence of the infection or is it a reinfection? In the way of prophylaxis, should our energies be directed the more against the predisposing causes or against the specific fungi in the premises, and have we been overemphasizing fungicidal chemicals in treatment?

These questions have been largely unanswered because many clinical studies made in clinics and offices and directed toward their solution have not included suitable control series. When these questions assumed importance among the armed forces there became available men requiring treatment and in sufficient numbers to provide treated and control groups of adequate size, a type of discipline which made control and follow-up studies possible, a reasonably uniform environment, well trained dermatologists and mycologists, professional assistants, and facilities and funds adequate for the study. Under these favorable conditions a better understanding of dermatophytosis of the foot has been gained and some advances in its control have been made. This report can cover only a few of the many studies which have been made under these conditions. By way of indicating the wealth of material, Peck studied 2,123 individuals in industry, Keeney had access to 128 naval cadets or more, and Weidman and Glass employed 116 prisoners at a penitentiary.

ETIOLOGY

After it was shown that dermatophytes [1] were the cause of certain intertrigos of the toes, it was assumed by many physicians that they were the cause in all cases of this condition. It now appears certain that bacteria [2] may be the cause in some cases. Hopkins [3] was unable to demonstrate fungi even after repeated microscopic examinations in as many as 30 per cent of military personnel with lesions of the feet. He concluded that

Most of the section on fungicide testing is unpublished. It was conducted by a subcommittee of the American Public Health Association working at the National Institute of Health. Drs. C. M. Brewer, E. G. Klarmann and G. G. Slocum were members of this subcommittee, and Dr. C. W. Emmons was the fourth member. The National Institute of Health gave permission for the publication of the results in advance of its own reports.

1. The commonest species in the United States are: 1. Trichophyton interdigitale (*synonyms Trichophyton gypseum, Trichophyton mentagrophytes,* Kauffman-Wolff fungus). "Trichophyton interdigitale" has been selected for the purposes of this paper because it is the more widely employed name. 2. Trichophyton purpureum (synonyms Trichophyton rubrum, Epidermophyton *rubrum and others*). 3. Epidermophyton inguinale (synonym Epidermophyton floccosum). A complete statement of synonyms can be found in the Manual of Clinical Mycology by Conant and others, Philadelphia, W. B. Saunders Company, 1944.

3. Hopkins, J. G.; Hillegas, A. B.; Camp, E.; Ledin, R. B., and Rebell, G.: Treatment and Prevention of Dermatophytosis and Related Conditions, Bull. U. S. Army M. Dept., June 1944, No. 77, p. 42.

some of these nonmycotic lesions were due to infection by Staphylococcus aureus or to sensitization to S. aureus, shoe polish, fungicides, antiseptics and similar sensitizing substances. Hypostasis due to long standing and trauma account for other groups of these disturbances of the feet. However, the extreme point of view of Benedek [4] that fungi are only secondary invaders not etiologically related to lesions of the feet is untenable in view of the many instances of experimental production of dermatophytosis.[5] The facts seem to be that fungi cause the majority of intertrigos of the toes but that bacteria and sensitization are responsible for a considerable number. Improper hygiene of the feet seems to be an important predisposing factor.[6] The too frequent acceptance of the diagnosis of dermatophytid of the hands has likewise given place to a recognition of the role of sensitization to nonmycotic agents in the majority of these cutaneous lesions.

Recurrence versus Reinfection.—This subject is still under lively discussion. Every physician is familiar with the apparent cures, followed by outbursts. The answer to the question naturally hinges on whether the causative fungi are eradicated in the apparently cured cases or still remain on the skin, quiescent but still viable. The evidence from the laboratory is contradictory. Some authors have cultured the fungi from apparently normal feet, while others were unable to do so. On one point all dermatologists are agreed, namely that fungi can remain for long periods within diseased nails without provoking an inflammatory reaction; the nails thus constitute an innocent looking reservoir. On the other hand, with the fungi so ubiquitous on man and viable for as long as 433 days in dry scales,[5] it appears logical that some reattacks must be due to reinfection: the environment harbors fungi.

It would be desirable to know the relative importance of recurrence and reinfection, but that information is not now available because of the difficulty of determining that treatment has actually eradicated the fungus from the skin. This cannot be proved by culture studies because there is a significant number of failures to isolate a fungus when it is known to be present and it is impossible to take an adequate sample for the detection of a remote and inapparent focus. The role of reinfection, on the other hand, cannot be disregarded because we cannot know certainly that the fungus has been removed from shoes, clothing, floors and the like.

One of us (G. M. L.) believes that the species of fungus concerned offers an answer. Thus, Epidermophyton inguinale infections are easily cured; therefore a second attack should be a reinfection. On the other hand, Trichophyton purpureum ones are so resistant to treatment that some of the fungi remain viable on the skin and accordingly a reattack would classify as a recurrence. In a case of infection with Trichophyton interdigitale it may be either way; the fungi may or may not remain on the skin, depending on the manner in which the patient has been treated. Thus, an active tissue response to treatment leads to the eradication of the fungus. In any event, studies by Hopkins and his associates [3] indicated that no reliance could be placed on attempts to prevent reinfection. Dermatophytosis flared up when hot weather, heavy shoes and violent exercise reactivated quiescent lesions on the patient's own feet. Obviously, prophylaxis of dermatophytosis should be a two pronged drive; first and foremost, to destroy completely the fungi on the skin and, second in importance, to destroy them in shoes and other environment. It is such a short step between shoes and pedal skin that the two must be handled together.

PROPHYLAXIS

Sterilization of Previously Worn Shoes.—Obviously, rather severe limitations are placed on the choice of sterilizing agents when dealing with leather. Theoretically, gases are preferable to liquids, but Greene [7] found that even formaldehyde vapor did not satisfactorily penetrate into the cracks of the shoes. Accordingly, he devised the following methods for mass sterilization and reconditioning as needed in institutions and military establishments where suitable apparatus was available. Immersion in 1 per cent formaldehyde solution for five minutes sterilizes the entire shoe. For supplementary mechanical cleansing the shoes were washed in a 0.3 per cent soap solution, followed by washing in water for two minutes. The last traces of formaldehyde can be neutralized in a two minute bath of 0.5 per cent sodium bisulfite, but this is probably unnecessary. Pliability was restored by a bath in a 10 per cent oil emulsion for two minutes; 0.5 pentachlorophenol was incorporated in it to prevent development of mold during drying of the shoes. As to the choice of oils, the National Oil Products Company's "Tanoyle No. 1052" (a "cationic oil" consisting of a mixture of polyethyleneoamines, fatty oil and mineral oil) was preferred. Neatsfoot oil was emulsified with a 2 per cent solution of Armour and Company's "A. M. Coco B acetate" (coconut oil fatty acid converted to its acetate salt) but needed agitation to maintain the emulsion.

For the sterilization of small numbers of shoes, the following method can be substituted:

1. Cleanse the shoes of any extraneous débris or dirt. Use any mild soap and water.
2. Dry as well as possible with a dry cloth.
3. Put in each shoe a pad of cotton; spread it out to make an insole.
4. Pour onto this insole (in each shoe) 1 teaspoon of solution of formaldehyde U. S. P. diluted 1 : 10.
5. Put the shoes in a paper box, close the lid and wrap in paper. Allow the shoes to remain in this box for at least six hours.
6. Remove them from the box, throw away the cotton and air the shoes for twenty-four hours.
7. Apply saddle or harness soap liberally to all parts of the shoes, inside and out. Allow this to dry.
8. Polish shoes as usual and wear.

Hygiene of the Feet.—The prophylactic value of foot baths is probably negligible. Early reports of their value may have failed to take into account the increased and beneficial attention to foot hygiene which may have been but incidental to education about the condition and to the use of the foot bath. There are three vulnerable points; viz., maintenance of the chemical at fungicidal concentration, the short period of exposure and enforcement of use. Sodium hyposulfite, sometimes used, is completely worthless in in vitro tests of fungicidal value, and sodium hypochlorite deteriorates rapidly. The period of exposure is too short to be of value, Bonar and Dreyer [8] having demonstrated that Trichophyton in

epidermal scales is killed by sodium hypochlorite only after an exposure of an hour. Finally, enforcement of use is difficult because of the reasonable aversion of persons to walking through a common, sometimes filthy, foot bath.

One of the more newly developed fungicides, sodium propionate, may be employed in 1 per cent concentration in powdered talc.

TREATMENT

The general hygienic measures already indicated should accompany the active, fungicidal treatment. As to the latter, the most important single item is conservatism. Do not overtreat. Every dermatologist is familiar with the severe chemical dermatitides which his patients often exhibit at the first visit and which must be corrected before proceeding in the more or less conventional ways. Such "horrible examples" are the result of disregard of the long established dictum that acute dermatoses should be treated with the mildest types of local applications; stronger, stimulating ones should be reserved for lesions in a subacute or chronic stage.

Accordingly, the choice of fungicide will vary notably in dermatophytosis, depending on the location of the lesion and the form that the inflammation takes in the individual case. This, together with methods of application, is available in standard textbooks[9] and in the very recent report by Hopkins and his associates.[3] For the purpose of this communication, only the results of tests of new fungicides will be recorded.

The most promising of these is paralleled in the use of sodium or calcium propionate in bread dough and dairy products for the purpose of inhibiting the growth of molds; they are marketed under the trade name of "Mycoban." After Peck and Rosenfeld[10] had demonstrated that propionate inhibited human pathogenic fungi, Keeney and Broyles[11] found it effective against various forms of ringworm and in otomycosis, thrush and blacktongue. It is used in 10 per cent concentration, both powder and ointment. Ointment was used at night on toes and soles; in the morning it was removed and the powder was dusted on. Their tabulation indicates excellent results. Lately, Keeney and his co-workers[12] have reemphasized the value of propionate-propionic acid ointment as satisfying the qualifications, "enumerated in this report, of an ideal preparation for the treatment of tinea pedis." They were inclined to prefer it to undecylenate-undecylenic acid ointment. Moreover, in some respects it was as effective as penicillin against bacteria.

At a penitentiary, Weidman and Glass[13] compared six different forms of treatment on 116 prisoners. Whitfield's ointment, as well as 10 per cent boric acid in powdered talc, were included as standards of comparison, more or less, against four proprietary substances: Zephiran (a mixture of alkyl dimethyl-benzyl ammonium chlorides), Cresatin (metacresyl acetate), Pomeio (potassium mercuric iodide) and Iodolate (iodocholeate). Surprisingly, the boric acid powder was highly efficient. Cresatin was equally efficient, while Whitfield's ointment followed rather closely. The remaining three preparations were found unsuitable in their hands. These studies were conducted in the winter, when the lesions were relatively quiescent. They renew attention to the value of boric acid and place Cresatin on the list of fungicidal agents that are useful against dermatophytosis.

Effects of Sweat on Fungicidal Value of Chemicals.—This subject has not been investigated but should be checked in future studies, just as the role of serum in modifying the effectiveness of certain disinfectants and antiseptics is well known in the bacteriologic field. On the one hand, sweat is said to have fungicidal value of itself;[14] on the other hand, sweaty feet predispose to dermatophytosis. An unrelated consideration is the effect that it may have on the fungicide.

Similarly, the role of detergents which might be combined with fungicides and which are applied to the skin as simple mechanical cleansers will have to be established. They may be incompatible. Data in the bacteriologic field will be found in papers by Baker, Harrison and Miller.[15]

STANDARDS FOR IN VITRO FUNGICIDE TESTING

The subject of standards for in vitro fungicide testing was brought to a head by the war. Several methods of testing fungicides had been advanced prior to the emergency, but all were open to criticism. A serious attempt had not been made to resolve the various methods into a standard one such as the phenol coefficient for bacterial disinfectants and antiseptics is. It is obvious that conditions among the fungi are different. Special consideration must be given to (1) the kinds of fungous cells (such as conidia) that are to be employed as test objects, (2) the selection of the standard fungicide that will be reasonably representative of fungicides (iodine, benzoic acid) and (3) the choice between liquid or solid mediums. These problems in in vitro tests, although they have been approached, have not been solved in sufficient completeness and detail to permit the establishment of a universally useful, single, standard fungicidal test, but headway is being made. A systematic and searching attack is being made in the matter by a subcommittee of the American Public Health Association composed of C. M. Brewer, C. W. Emmons (chairman), J. G. Hopkins, E. G. Klarmann, G. G. Slocum and F. D. Weidman.

It is urgent that a standard test be established promptly. Thus, with the prospect of large sales to our several war departments, manufacturers have been and are still asking themselves whether their proprietary disinfectants and antiseptics have value also against fungi. On inquiry they find that there is not any fungicide test that has been accepted as standard and that the routine phenol coefficient test of the bacteriologist will not suffice. True, the Bureau of Ships made a praiseworthy attempt,[16] but it erred at least in selecting "Trichophyton rosaceum" as the test object. This point will be covered further in this review and has been corrected by the Bureau of Ships. Incidentally, the circular just cited may serve, pro tem, as a pattern or basis of consideration for fungicide testing in all its aspects.

16 Dec. 1[illegible], Circular SNDb (1st), paragraph F 2b.

(*m*) Mycologic Checks on Therapeutic Results: More than in the case of the laboratory examinations for purposes of diagnosis, these will have value only of a kind supplementary to the clinical opinions because of the increased difficulty in laboratory demonstration of fungi in treated lesions. At the conclusion of therapy they should be made on the "cured" and "nearly cured" patients and again on the cured patients four weeks after cure. Positive results will have larger definitive value because they will indicate that the fungicide has not killed; negative ones will have the same (and lesser) significance as under other circumstances, namely that there is still an outside chance that fungi are still present but not demonstrable. In any event this mycologic check should be performed if for no other reason than to have the data at hand when making final evaluations. They may turn the balance when wavering in a decision as to cure or no cure. The competence of the examiner in recognition of fungi is of paramount importance.

(*n*) Grading of Results: "Cured," "almost cured," "improved," "stationary" and "worse" are suggested, but each worker is at liberty to select any system that suits his purposes. All workers, though, should go on record to themselves beforehand for their own guidance as to the criteria that they should follow in grading; from this there should be no deviation later. A subdivision like this into five grades reduces the number of cases available for subsequent statistical purposes and illustrates once again the necessity for numerous patients to begin with. Opinions of patients as to results should not be depended on too much; in cases of doubt they should be discounted. Patients commonly regard themselves as cured when itching ceases. It will be conducive to accuracy if the physician has an assistant who will independently grade the results, the final grading being decided in consultation on the spot

3. *Toxicity Tests.*—These should be performed depending on the individual circumstances surrounding the chemical concerned. Where there is a hazard the Bureau of Ships circular entitled "Disinfectant, Germicide and Fungicide," page 4, paragraph F.-2d should be followed. Ten healthy adult albino rats weighing between 150 and 250 Gm. should be employed, none pregnant. They should be fed as usual. Three-tenths cc. of the fungicide (standard strength) per kilogram of body weight should be slowly inserted obliquely into the peritoneal cavity. The animal should then be given the usual food and water and observed for untoward effects for seventy-two hours.

OTHER CONSIDERATIONS IN DERMATOPHYTOSIS

The "One Foot Treated, Other Foot Control" Technic.—Goldman and his associates [24] selected this plan in their studies of two phenylmercuric compounds. Its merit is by no means convincing. Considering the fact that the severity of ringworm on the one foot will seldom equal that on the other, and that these authors themselves observed spontaneous clearing of the control foot *pari passu* with the treated one, this method should be disregarded.

SCOPE OF SENSITIZATION IN DERMATOPHYTOSIS (EXTENDING TO BUERGER'S DISEASE?)

Although the scope of sensitization in dermatophytosis is not currently connected with war activities, it can have a bearing on members of the war forces both during and after the war. Claims for war disability may hinge on this newer development. Thompson [25] contends that the allergy of dermatophytosis may extend as far as to induce peripheral vascular disease which is of the order of, if not quite, Buerger's disease. Naide [26] has supported this thesis.

INDUSTRIAL MYCOSES IN WARTIME

Even prior to Pearl Harbor, dermatophytosis commanded attention because it was such a factor in workmen's compensation claims. After that, the additional factor of manpower in industry entered. The challenge to factory medical personnel was now shared by the United States Public Health Service. Peck, Botvinick and Schwartz [27] found that, although the fungi under laboratory conditions remained viable for at least seventy-two hours on cement, wood and copper impregnated flooring materials, the fungi could not be isolated from the flooring under field conditions. On pine wood it was viable for one week (the other flooring materials were not tested at this interval). It is not surprising to learn that native fungicidal substances are negligible in wood and cement, although more might have been expected from copper. It appears, then, that such flooring "is a possible but not likely source" for dermatophytosis and that copper impregnated flooring is not superior to others and scarcely merits the extra expense.

It is somewhat surprising that only 28 per cent of the 2,123 persons examined by Peck and his associates exhibited unequivocal clinical dermatophytosis, because statistics in other groups (students, inmates of institutions, members of the armed forces) have ranged consistently around 65 per cent. These workers were perhaps overconservative in diagnosing dermatophytosis, as they secured cultures from a goodly number of their "doubtful" cases. From calculations which we made on Peck's materials it appears reasonable to assume that upward of 50 per cent of the personnel in industry is affected by the condition.

Compulsory showers, with foot baths of hypochlorite solution, evidently did not reduce the incidence of dermatophytosis, as judged by a control group which did not receive showers. The tests lose much significance, though, because the foot baths were not rigidly administered.

It is surprising but gratifying that dermatophytosis and its allergic manifestations were not important factors in lost time among industrial workers. Most important too is the evidence of Peck and his associates in the dispute whether the allergy of dermatophytosis predisposes to the development of contact dermatitis. They concluded that it did not predispose. Industrialists should not discriminate against workers with positive Trichophytin reactions in the fear that they may be more susceptible to contact dermatitides. If 42 per cent of workers have a positive reaction, the risk would have to be accepted in any event; industry at large could scarcely visit unemployment on such a large fraction of labor. Naturally these considerations apply also to members of the armed forces in the establishments which are indispensable in the highly mechanized warfare of today, whether today or post war when disability allowances will have to be adjudicated

SELF TREATMENT

The treacherous ground of self treatment has been thoroughly explored by us. Although there appears to be a consensus among dermatologists against self treatment, it remains that a large section of the public will still treat itself. It buys aspirin for headache and "rheumatic pains" and will use "rhinitis" tablets and benzedrine inhalers for colds in the head. Similarly, it will attempt to avoid proper medical treatment by buying proprietary preparations for athlete's foot as long as the condition remains in the milder form that does not incapacitate. Whitfield's ointment is probably more widely known than other forms of treatment, barring the ones widely advertised by proprietary houses. It must be granted that it is harmless in the hands of many people, but a canvass of his local dermatologic society by one of us (F. D. W.) shows that there is still a large factor of danger. Thus we are defeated in our attempts to compile a list of medicaments which could be recommended safely. Only one substance, boric acid, has therapeutic value and is safe for public use. Even here there is a hazard: the public may depend on it too much; i. e., for severer forms which demand the services of the physician.

It is in this light that the program which follows has been arranged. Naturally, prophylaxis is not as highly liable to criticism as treatment, and we feel quite satisfied with the recommendations under this heading. Under the heading of treatment, though, the patient is charged with the responsibility of deciding whether his case is a mild one, and few individuals are capable of even approximating an evaluation of their diseases—even athlete's foot. This, though, seems to be the lesser of two evils, i. e. whether to recommend a substance like boric acid which can do a minimum of harm, or to condemn any and all forms of treatment. The public is bound to practice self treatment of some kind and it may be better to encourage the use of boric acid than for the public to continue the use of iodine, camphorphenol mixtures and other damaging chemicals.

In any event, if self treatment is to be attempted at all it should not exceed the principles embodied in the following abstract. It represents a digest, adapted from the body of this review, which leads to practical therapeutic applications. It must not be regarded as a self-sufficient exposition of the matter; it is subject to all of the qualifications indicated in the body of this paper.

Prophylaxis.—1. Keep the feet clean and dry, with special attention to places between the toes. Dry these carefully but not so hard as to irritate the skin.

2. Air shoes and socks when not in use.

3. Under special conditions, keep the feet elevated when at rest (where the conditions predispose to intertrigo, as with marching soldiers).

4. Shoes should be selected that are as light and well aerated as is compatible with working conditions.

5. A dusting powder consisting of 10 per cent boric acid in powdered talc should be dusted on the feet and between the toes every night and morning.

Treatment.—1. Only the mild lesions that occur between the toes should be treated by the patient himself; i. e., where the lesions exhibit only scaliness and perhaps mild redness and fissuring. Considerable redness, moisture, pustule formation or pain call for the attention of the physician and the physician only. The patient must err on the safe side.

2. Such mild cases can be treated as follows:

(*a*) Observe regulations just laid down for prophylaxis.

(*b*) Nothing is safe as a local application except the boric acid foot powder mentioned under prophylaxis. If there is not any improvement within two weeks, consult a physician.

(*c*) Under no circumstances should the patient yield to the well meant recommendations of friends and to advertisements. Preparations containing iodine, mercury or sulfur are particularly dangerous, and sulfonamide preparations are notorious because they so frequently sensitize the individual to sulfonamide drugs which may be imperatively indicated later for a really serious ailment.

CONCLUSIONS

The war has added fresh importance to dermatophytosis. This has stepped up the tempo of investigation with the natural result that certain old ideas have been confirmed, others crystallized or nearly crystallized, some disproved and others newly established. Much of this work has a foundation of the highest reliability because under war conditions it was possible to recruit expert dermatologists and mycologists, together with an adequate supply of assistants, clinical materials, laboratory facilities and funds. The results accordingly, have high and probably enduring significance.

In the way of confirming old ideas, the incidence of dermatophytosis was again found to be high. The hygiene of the feet was paramount both in prophylaxis and in treatment, with the emphasis on the detrimental role of sweat. The "old reliable" Whitfield's ointment, and also boric acid powder, stood up well as fungicide preparations when compared with newer ones like sodium propionate and Cresatin.

Changes in concepts appeared; first, the current of opinion is sweeping bacteria into the scene as the cause of many infectious intertrigos that have hitherto been taken for granted as mycotic. Other foot conditions are due to sensitization to local applications such as shoe polish and medicaments, and to long standing hypostasis and trauma. As to the notorious repetition of attacks in dermatophytosis, opinion is swinging to the belief that they represent recurrences; the extent to which they are reinfections is probably minor. This point is not merely academic; it bears on prophylaxis by indicating that efforts should be directed at the feet more than the environment, thus saving bother and expense. Foot baths (hypochlorite and hyposulfite) are becoming discredited. Evidence has been submitted in the controversy whether dermatophytosis predisposes to contact dermatitis; namely, that it does not. This question is important for adjudicating disability claims in the armed forces and elsewhere.

Fresh information is represented, first, in the establishment of a definite technic for sterilization of shoes. In treatment, sodium propionate, undecylenic acid and Cresatin (metacresylacetate) have emerged as useful fungicides. Medicine is now surprised by the theories that Buerger's disease is an allergic expression of dermatophytosis and that little manpower was lost in industry as the result of dermatophytosis. Matters are rapidly coming to a head in the establishment of a standard method for testing fungicides, at least for dermatophytosis, and an outline has been submitted for the clinical evaluation of fungicides which should be useful to manufacturers and others. Too, a venture was made into the dangerous field of self treatment.

The foregoing record of accomplishment is a credit indeed to the numerous investigators who played a part where they could in the American war effort. Their benefits to medicine will far outlast the war.

NEOSTIGMINE AND NEUROMUSCULAR DYSFUNCTION

Neostigmine (prostigmine), a synthetic drug, was first used in the form of the methylsulfate for stimulating the intestinal tract and thus overcoming postoperative atony. A second and even more striking clinical application was soon discovered, based on its effect on the symptoms of myasthenia gravis. Even when the drug is given by mouth as neostigmine bromide, the decrease in muscle fatigue is often striking. Moreover, neostigmine will apparently inhibit cholinesterase, the chemical agent that destroys acetylcholine, an important factor in neuromuscular transmissions. Acetylcholine is found in nerve tissue and at the myoneural junction. One theory accounts for the effectiveness of neostigmine in myasthenia gravis on the assumption that inhibition of the cholinesterase at the junction permits an impulse to pass more readily and effectively from the nerve to the muscle. Not all investigators accept this explanation, but none disagree with regard to the powerful effect of the drug when given to patients with myasthenia gravis. There is some evidence, however, that neostigmine may affect spinal centers, as well as the myoneural junction, and possibly centers in the medulla or cerebrum. Kremer,[1] by using intrathecal injections of neostigmine, produced loss of muscle tone in man.

These studies have led to a trial of neostigmine in a wide variety of diseases in which muscular paralysis, spasm, tension or spasticity and cramps, painful or otherwise, are important symptoms. In 1944 alone studies were published also on the use of the drug in anoxia, homosexuality, pregnancy, amenorrhea, arthritis, goiter, morphine analgesia, colon dilatation and poliomyelitis.

Kabat and Knapp[2] have reported studies on patients with poliomyelitis indicating relaxation of muscular spasms, relief from pain, increasing the strength and improvement in muscular coordination after treatment with neostigmine. Trommer and Cohen[3] also noted good effect in the treatment of muscular spasm in patients with rheumatoid arthritis and some associated conditions. Kabat[4] has also indicated that this drug may have a useful function in treating hemiplegia, facial paralysis, cerebral palsy, chronic rheumatoid arthritis and subacromial bursitis. Over 50 patients with these various disorders were treated by subcutaneous injections of 1 mg. of neostigmine methylsulfate with 0.65 mg. or 0.43 mg. of atropine sulfate.

In the series treated by Kabat there were 8 patients suffering from persistent joint stiffness, pain and limitation of motion following various types of fractures. In 7 of these cases significant improvement was noted during one to two weeks of treatment. Seven patients with hemiplegia were observed with a favorable relief of their spasticity while under treatment. Similar results were reported in patients with hemiplegia due to cerebral palsy of the congenital type. Six patients with chronic rheumatoid arthritis were relieved in various degrees and, in general, Kabat felt that the results were encouraging enough to warrant further investigation with control procedures and other means of evaluation.

Schaubel[5] also has observed encouraging results with a similar form of treatment in cases of spastic cerebral paralysis.

Watkins and Brazier[6] have recently attempted to evaluate the muscle spasm in poliomyelitis by electromyographic studies. In the course of their work, seventy tests were made before and after the intramuscular injection of 1.6 mg. of neostigmine methylsulfate. At the period of maximum effectiveness of the drug, namely twenty minutes after the injection, there was less irritability exhibited in the electromyogram than during the control period. They point out that, in the treatment of poliomyelitis, neostigmine has not been used in a sufficient number of instances to justify the drawing of definite conclusions in regard to its value. Watkins and Brazier observed, moreover, the effect of only a single application and not the effect of repeated injections as used by Kabat. They conclude that the degree of change was not great enough to indicate a specific effect by neostigmine on muscle spasm. Two articles reviewing the effects of neo-

stigmine on patients with poliomyelitis appeared in THE JOURNAL last week.[7]

Although neostigmine may be of value in treating conditions other than intestinal atony and myasthenia gravis, the work presented by Kabat and others on its use in a large number of unrelated conditions is insufficient for critical evaluation. More carefully controlled studies will be required before a definitive statement with regard to its usefulness can be made.

HEALTH AND PHYSICAL EDUCATION LEGISLATION IN OREGON

The Forty-Third Legislative Assembly of the State of Oregon passed House Bill No. 53, entitled "An act to provide for programs of health instruction and physical education in all elementary and high schools of the state, to provide for the planning, supervision, direction and evaluation of such programs by the superintendent of public instruction, and appropriating money therefor . . ." and to repeal certain other sections of existing statutes. The bill, if one may judge from a story by Wilma Morrison in the Portland *Oregonian*, April 8, attracted little attention in the legislature and calls for only $26,000 a year from the taxpayers. The law provides that all school districts in the state of Oregon shall—not may—provide in their respective schools programs of health instruction and physical education for the development of health and physical fitness for all elementary and high school pupils in such schools. The purpose is to promote, develop and maintain among pupils at all levels "optimum physical growth, health and physical fitness." The bill prescribes what shall be included in health instruction programs, namely "personal hygiene, community health and sanitation, communicable diseases, nutrition, mental health, safety education, first aid, instruction in the choice and use of health services and health practices, instruction concerning the structure and functioning of the human body, the physiological effects of exercise, and such other instruction as the state superintendent of public instruction may deem important."

The program in Oregon is to be under the general direction of the superintendent of public instruction. Six mandatory functions are assigned to him: to (1) provide health examinations in the elementary and secondary schools, (2) provide and recommend program materials, (3) provide checks and standards by which the progress of individual pupils and the programs of schools can be evaluated and the schools rated "in terms of their meeting the purposes of this act," (4) coordinate the activities of governmental agencies which carry on functions in the schools related to the purposes of the act, (5) employ the necessary personnel and (6) make necessary rules and regulations.

Subordinate school officials in local governmental units are made responsible for carrying out the rules and regulations issued by the superintendent of public instruction. Exemptions are provided for constitutional or religious objectors who may wish to be excused from participation in the program outlined by the act.

Responsible officials in Oregon met at once in order to put the provisions of the act into effect. The superintendent of schools has created an Oregon Joint Committee on Health and Physical Fitness, headed by Dr. R. W. Leighton, dean of physical education at the University of Oregon. This is the group which formulated the bill. A prime force in getting the legislation passed was the Oregon State Federation of Women's Clubs. The appropriation is small, although Dean Leighton says it will be sufficient. With existing buildings and equipment, supervision from trained personnel and the setting up of standards, results should follow.

The Oregon act is said to be the first legislation of its type in any state. Legislation, or even the effective functioning of the program under such legislation as this, will not necessarily eliminate all physical unfitness and all sources of poor health. Much can undoubtedly be accomplished, but not in a year or in two years. Measurable results may take ten years. In the meantime, those who work in the program and those who appropriate money for its support must not become discouraged. Even with the best program functioning at the highest possible efficiency some conditions are not remediable in the present state of medical knowledge. The time is ripe for great progress toward improved health and physical fitness.

Current Comment

TRANSMISSION OF A SHOCK PRODUCING FACTOR

Shock is still one of the important causes of death of the injured soldier. While the symptoms and various physiologic responses of the shock syndrome are well known, the causative factors are still in doubt. One of the difficulties facing experiment in this field is the production of a reproducible shock syndrome. This has been accomplished to some extent by either traumatizing the leg of an experimental animal or by leaving a tourniquet on the leg for a time and then removing it. By using such a standardized technic Cannon and Bayliss concluded that there is a toxic substance emitted from the injured tissue which is responsible for the production of the general shock syndrome. Additional work has been attempted to show that a toxic agent is responsible for the initial

of shock. Recently Rapport, Guild and Canzanelli [1] produced shock by allowing a tourniquet to remain on the leg of a rabbit for two hours. To show the presence of a toxic substance the rabbit's leg was joined into the general circulation of a second, normal, rabbit. Thus the traumatized leg received all of its blood supply from the normal rabbit's circulation and in turn contributed its blood and tissue metabolites to the normal rabbit's circulation. This experimental procedure, called "cross circulation," is a common though difficult physiologic testing device. In the control experiments in which normal legs were cross circulated with a normal rabbit the animals survived for fifteen and a half hours. When the tourniquet treated legs were cross circulated with normal rabbits the animals survived only four and three-tenths hours. These observations seem to point to the possibility that a shock producing factor was transmitted in the blood. The knowledge that a toxic substance may be liberated from an injury which is of such extent that the host is thrown into shock may have considerable directive influence both in the prevention and in the treatment of the shock syndrome.

PROGNOSIS IN THROMBOCYTOPENIA

In a study of 30 cases of thrombocytopenic purpura Schwartz [1] showed that increased numbers of eosinophils in the bone marrow signify a favorable prognosis for spontaneous recovery, while scant numbers suggest a chronic course and the necessity for splenectomy. The marrow eosinophilia probably indicates an allergic state, while thrombocytopenia represents a sensitization reaction involving the megakaryocytes. Neutrophils were selected as cells for the basis of comparison, because eosinophils presumably arise from the same stem and because specific stimulation of the granulocytes does not occur in thrombocytopenic purpura. The number of eosinophils observed in counting 1,000 granulocytes of the neutrophilic series was determined on the basis of these studies. Schwartz feels that it is possible to divide cases of primary thrombocytopenic purpura, at least from the prognostic point of view, into two types: (*a*) those with increased numbers of eosinophils in the marrow and (*b*) those without increase in marrow eosinophils. Cases with high marrow eosinophils are probably due to sensitivity, are usually acute in onset and course, occasionally follow infection or ingestion of drugs or allergenic foods, have relatively benign course and are followed by complete clinical and hematologic recovery. Splenectomy is not necessary in these cases, and blood transfusions hasten recovery. Prognosis in cases with few eosinophils, arbitrarily below 50, are of poor prognostic outlook and require splenectomy. Correlation was not found between the marrow eosinophilia and peripheral blood eosinophilia. Schwartz is aware that prognoses based on the numerical variation of a certain cell must be made with caution and that a number of factors can influence the bone marrow at a given moment. It is suggested, however, that certain correlations do exist and that these may be utilized in helping to make prognosis and treatment of thrombocytopenic purpura more rational.

THE 1942-1943 EPIDEMIC OF INFANTILE PARALYSIS IN MALTA

In the middle of November 1942 an epidemic of infantile paralysis began in Malta, reached its height in the latter part of December and was over by March 1, 1943. The outbreak included 483 paralytic cases, 426 in civilians and 57 in military service men. Owing mainly to circumstances connected with the bombardment of Malta, satisfactory study could not be made of the occurrence of civilian nonparalytic cases. Of the 483 cases, which include 40 simultaneous cases on the neighboring island of Gozo, 397 (82 per cent) occurred in children under 5 years of age. The case death rate in the civilians was 6.1 and in the service men (United Kingdom) 19.3 per cent. These and other facts to be cited are taken from the report of epidemiologic features of the outbreak by Seddon and his co-workers.[1] Like studies of other epidemics in isolated regions, their study presents results of interest in regard to the origin and spread of outbreaks of infantile paralysis. After thorough consideration of the circumstances, some of which are quite unusual, it seemed safe to conclude that the spread of the Malta epidemic was not promoted by the great overcrowding at that time, by the lack of food and vitamins, by possible contamination of food and water from the use of sewage for manuring or by the consumption of dried milk. As the epidemic developed rapidly at a time when flies were less numerous than at other seasons, "it is tolerably certain that the disease was not spread by flies." That the virus of the epidemic was an indigenous strain is indicated by the facts that a few sporadic cases of infantile paralysis have developed in Malta over many years, that civilians were attacked first, that the adult Maltese almost wholly escaped and that there was no evidence of the virus being brought in by service men. Seddon and his associates point out that the causal strain "cannot have differed greatly from the normal strain, since its pathogenicity was confined to the more susceptible groups of the indigenous population, who had presumably not had time or opportunity to become completely protected by the normal process of latent infection." They also note that the pattern of the epidemic corresponds to that of a respiratory type of infection. But why did the disease assume the paralytic form? "The virus is constantly with us, constantly infecting us, but only rarely getting through to attack the central nervous system. And the circumstances in which it loses its temper, so to speak, and gores us to the marrow we simply do not know." [2]

MEDICINE AND THE WAR

ARMY

ARMY MEDICAL OFFICERS REQUEST ROTATION OF ASSIGNMENTS IN SERVICE

NOTE.—The following communication received from five medical officers of the United States Army in Europe, including a major and four captains, is published so that it may receive consideration by the medical profession and by the officers in the Office of the Surgeon General. Contrary to our usual custom, the letter is printed without signature, since the officers specifically request that their signatures be not included. Certainly the point raised merits consideration.—ED.

To the Editor:—We are army medical officers on active duty for varying lengths of time ranging from thirty-two months to forty-eight months at a fighter station in England since November 1943 and are now about to go to Germany in the Army of Occupation. When we shall be relieved is a matter of speculation. Frankly, we've been thinking lately about the lack of rotation for medical officers and naturally the question arises "Are there not sufficient doctors in the United States to meet our country's military demands?" We think there are.

There are many conflicting reports reaching us concerning the procurement of medical officers for military service, none of which, however, are of an official nature. In order to ease our minds, and to be sure they need easing, we medical officers would like some clarification of the subject if possible. We would like the following information answered:

(*a*) The number of medical officers on active army service and naval service (excluding Veterans Administration).

(*b*) The number of medical school graduates since 1941 and the percentage of these in army service and naval service.

(*c*) The number of doctors under 45 years of age in civilian practice.

(*d*) The number of doctors being procured monthly for army service and naval service.

(*e*) The actual strength of the Army and Navy Medical Corps and the proposed strength necessary to defeat Japan.

(*f*) The number of medical officers in the Army and Navy being discharged monthly exclusive of those discharged for incapacitating medical defects.

We medical officers, like thousands of other doctors, entered the service voluntarily with the sincere belief that it was our duty and with the further belief that it was our war. We further believe that it is the war of everybody in the United States and that equal responsibility exists for every one to share in the conflict. In other words, from the view of the doctor in service, it is as much Dr. Jones's war as it is Dr. Smith's war. We are all familiar with the apparent ease with which many individuals escape military service and are of the opinion that the fault more often than not lies in our administrating agencies. We feel that inefficient medical administration has gone far enough and that if it is permitted to continue unchecked it will affect not only the medical future of the physician but also that of the layman.

We doctors in the service consider it our duty and privilege to attend the sick and wounded and would continue to feel that way if we knew we were not being forgotten. Reports are now reaching us that many doctors coming out of internships are permitted to go on their merry way into residencies, hospital appointments and practice and that there are many men of our age and training still in our home towns, unmolested by our procurement agency. If this is correct and it appears so, what about us already in service. Are we to carry the whole burden? Or isn't it their war too?

It appears now that officers are to be discharged on the *point system*, that is all officers except medical officers—why? Are medical officers now in service to be penalized for taking the trouble and sacrifices to earn a medical education? We cannot help but believe that the procurement of medical officers should go on strenuously as long as war exists and as long as doctors are needed in the service, so that a definite surplus should exist. In this way a discharge system could apply to the medical profession also, and no one doctor need worry that no relief is coming. In most cases rotation would go on in a most natural manner. The civilian supply of doctors would not be affected, for outgoing medical officers would take the place in civilian practice of newly "procured" doctors. Further, no one proportion of doctors would suffer degeneration of their medical knowledge and ability, as is the case now with tactical unit doctors whose main duty is holding sick call, treating colds, corns, epidermophytosis and small lacerations. Any worthwhile cases by reason of the army medical setup must be transferred to station or general hospitals many miles away for definitive treatment. As a result we see these patients only when they are transferred and then discharged to duty. As is readily seen, any professional ability we possessed on entrance into the Army is steadily deteriorating.

It is discouraging for us to see a War Department statement in the public press that the army quota for medical officers is filled and that it is contemplated that the procurement of doctors is to relax. The quota should never be filled as long as war goes on. Any quota should include plans for release of medical officers long in the service. It is conceivable that every doctor in the United States, with certain exceptions for age, disability and the like, would see military service if the war should last long enough, which is as it should be if our premise that it is everybody's country and everybody's war is correct. At this point it appears obviously to be correct. Should Dr. Smith go to war for his home and family? The answer is yes! Furthermore, should he go to war also for Dr. Jones's home and family? The answer is no! Let Dr. Jones go to war for his own family and home. For certain reasons they may not be able to go together or at the same time, but let them go consecutively. Are the newly graduated doctors to be permitted to engage in prolonged internships and even longer residencies, not to mention civilian practice, simply because it is expedient for the Army to solve the medical problem in this manner, or are these young doctors to be inducted into the service so that we who have already served three or more years may be released to take care of the country's civilian needs, not to mention the furtherance of our own medical education, which in most cases has been interrupted by our army service.

There are many physicians of our own ages who have been declared so-called "essential" doctors simply because of circumstances placing them in such a position. Let us not forget that the fallacy of this premise lies in the fact not that the individual doctor is "essential" but that the position is essential. We feel that it is high time many of these men were inducted and replaced by medical officers with years of service, who will be only too eager to become "essential" in their stead.

We are submitting the foregoing plea for your consideration in the hope that our voices added to those of many other medical officers, who even though they have not made public their sentiments are of the same opinion, will bring about a change in the policy of the U. S. Army toward medical officers. We realize that this policy cannot be affected directly by you, but there is no question in our minds that the most potent organ for public feeling in medical circles is the American Medical Association and that if the minds of American medical men are expressed by the Association the effect of its influence must certainly bring about changes in higher places.

Our only desire is "Let us be heard!"

SURGICAL CONFERENCE OF THE SIXTH SERVICE COMMAND

A two day surgical conference, sponsored by the Sixth Service Command and open to the medical profession, will be held at the John B. Murphy Memorial Auditorium, American College of Surgeons, 50 East Erie Street, Chicago, July 27-28. The conference will be opened by Col. Don G. Hilldrup, surgeon, Sixth Service Command, and the following papers will be presented:

Symposiums on Reconstructive Operations for Large Defects in Bone, Major Joseph Farrington and Major Carl G. Caspers, Mayo General Hospital, Galesburg, Ill.; Lieut. Col. Thomas Horwitz and Lieut. Richard Lambert, Vaughan General Hospital, Hines, Ill.

Osteomyelitis of the Os Calcis, Lieut. Col. Francis M. McKeever and Capt. Ronald M. Buck, Percy Jones Hospital Center, Battle Creek, Mich.

Late Closure of War Wounds Associated with Chronic Osteomyelitis, Lieut. Col. Thomas Horwitz and Lieut. Richard Lambert, Vaughan General Hospital.

Preliminary Report on the Use of Sheet Nylon in Surgery, Lieut. Col. Philip Lewin and Capt. I. Joshua Speigel, Mayo General Hospital.

Treatment of Decubitus Ulcer in the Paralyzed Patient, Lieut. Col. John H. Gibbon Jr. and Lieut. Leslie W. Freeman, Mayo General Hospital.

Derangement of the Patellofemoral Joint (Motion Pictures), Major Francis E. West, Gardiner General Hospital, Chicago, and Lieut. Col. Ralph Soto-Hall, Headquarters Sixth Service Command, Chicago.

Visceral Injuries Associated with Compound Fractures of the Pelvis, Major George B. Sanders, Vaughan General Hospital.

Surgical Technic of Amputations, Capt. Curtis M. Hanson, Percy Jones Hospital Center.

Plastic Repair of Injuries of the Penile Urethra, Lieut. Col. Justin J. Cordonnier, Gardiner General Hospital.

Experience in the Treatment of 170 Traumatic Aneurysms, Major Harris B. Shumacker, Mayo General Hospital, followed by a discussion by Col. Daniel C. Elkin, Ashford General Hospital, White Sulphur Springs, W. Va., and Comdr. Emile Holman, U.S.N.R., Naval Hospital, Shoemaker, Calif.

Primary Malignant Tumors of Bone, Lieut. Col. Joseph C. Bell, Major Gilbert W. Heublein and Major Sylvan E. Moolten, Percy Jones Hospital Center.

Continuous Spinal Anesthesia (Motion Pictures), Major Edward B. Tuohy, Percy Jones Hospital Center.

Peripheral Nerve Lesions:

(a) New Methods of Electrodiagnosis, Lieut. Yvo T. Oester, Percy Jones Hospital Center.

(b) Surgery of the Posterior Interosseous Nerve, Lieut. Col. Frank E. Mayfield and Lieut John H. Mayer Jr., Percy Jones Hospital Center.

(c) Surgical Treatment of Injuries of the Brachial Plexus, Capt. I. Joshua Speigel and Lieut. Richard H. Upjohn, Mayo General Hospital.

(d) One Stage Operations for Combined Bone and Nerve Defects, Major Joseph Farrington and Capt. I. Joshua Speigel, Mayo General Hospital.

Heavy Resistance Exercises (Motion Pictures), Capt. Thomas L. DeLorme, Gardiner General Hospital.

Surgery of the Sympathetic System:

(a) Causalgia, Lieut. Col. Frank E. Mayfield and Lieut. Jack C. Ulmer, Percy Jones Hospital Center.

(b) Vascular Disorders, Major Harris B. Shumacker, Capt. Paul R. Olsson and Capt. Kenneth L. Carter, Mayo General Hospital.

In connection with the conference, the following scientific exhibits have been proposed:

Urolithiasis in Patients with Femoral Fractures, Lieut. Col. Louis D. Smith and Capt. Stuart W. Russell, Mayo General Hospital.

Glass Cloth for Wound Dressings, Capt. Ronald M. Buck, Percy Jones Hospital Center.

Orthopedic Splints, Lieut. Col. Philip Lewin, Mayo General Hospital.

Continuous Local Penicillin Therapy in Maxillary Sinusitis, Major Richard P. Good, Vaughan General Hospital.

Femoral Fractures, Lieut. Col. Ralph Soto Hall, Headquarters Sixth Service Command, and Lieut. Col. Thomas Horwitz, Vaughan General Hospital.

Artificial Eyes, Capt. R. M. Grassle, Gardiner General Hospital Occupational Therapy, Vaughan General Hospital.

Surgical Repair of Skull Defects with Tantalum Plate (a review of existing technics), Capt. I. Joshua Speigel and Lieut. Howard R. Hamlin, Mayo General Hospital.

Dermometry, Lieut. Howard R. Hamlin, Mayo General Hospital.

Tendon Transplants, Lieut. Col. Philip Lewin and Capt. Albert O. Singleton, Mayo General Hospital; Capt. Charles Schroeder, Camp Grant Station Hospital, Ill.

MISCELLANEOUS

KELLOGG FOUNDATION EDUCATION PROGRAM FOR VETERANS

The president of the W. K. Kellogg Foundation, Dr. Emory W. Morris, has announced a program under which funds will be available to assist a limited number of medical schools in the United States and Canada in developing comprehensive programs of graduate and postgraduate medical education. The immediate objective of the program is to help extend educational facilities for medical veterans. The long range objective is to encourage schools to develop permanent programs of postgraduate medical education.

The foundation has long been interested in medical education, especially at the postgraduate level. It believes that medical schools should accept the responsibility of providing not only good undergraduate and graduate medical education but also continuing or postgraduate education for all the physicians practicing in the area which the school serves.

Under this program requests for funds have already been approved for the University of Illinois College of Medicine, the University of Minnesota Medical School, the University of Oregon Medical School, Columbia University College of Physicians and Surgeons, Cornell University Medical College and New York University College of Medicine.

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

California

A. A. F. Regional and Convalescent Hospital, Santa Ana Army Air Base: The Cancer Problem in the Service, Lieut. J. S. Binkley, July 17.

A. A. F. Regional Hospital, March Field: Communicable Diseases, Major Norman Nixon and Capt. Charles D. Marple, July 17.

U. S. Naval Hospital, Long Beach: Penicillin and Its Use in Syphilis and Gonococcic Infections, Lieut. Comdr. W. W. Luemling, July 18.

U. S. Naval Air Training Station, San Diego: Classification and Diagnosis of the Anemias, Dr. Alvin Foord, July 20.

Station Hospital, Camp Cooke, Lompoc: Plastic Surgery in Defects of the Head and Neck, Dr. Edward S. Lamont, July 18.

Hoff General Hospital, Santa Barbara: Plastic Surgery in Defects of the Head and Neck, Dr. Edward S. Lamont, July 18.

Indiana

Billings General Hospital, Fort Benjamin Harrison: Peptic Ulcer, Gallbladder and Liver Diseases, Drs. W. D. Gatch and Lowell D. Snorf, July 18.

Wakeman General Hospital, Camp Atterbury: Chest Diseases and Diseases of the Larynx, Dr. Henry C. Sweany, July 18.

Wisconsin

Station Hospital, Camp McCoy: Plexus and Peripheral Nerve Injuries, Dr. Theodore C. Erickson, July 18.

Station Hospital, Truax Field: Endocrinology, Dr. W. D. Thompson, July 18.

Illinois

Gardiner General Hospital, Chicago: Bone and Joint Infections, Dr. David E. Markson and Major Sam W. Banks, July 18.

Station Hospital, Fort Sheridan: Repair of Bone in Fractures and Diseases, Drs. James R. Regan and Edwin Ryerson, July 18.

Vaughan General Hospital, Hines: Laboratory Diagnosis and Its Relationship to Medical and Surgical Treatment, Dr. Edwin F. Hirsch, July 18.

Mayo General Hospital, Galesburg: Blood Dyscrasias—Malaria—Filariasis, Dr. Raphael Isaacs and Col. Alexander Marble, July 18.

Regional Hospital, Chanute Field, Rantoul: Mental Hygiene and the Prevention of Neuroses in War, Col. William J. Blackwenn, July 18.

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

July 9, 1945.

Fulbright Advocates Formation of Bureau of Scientific Research

Senator Fulbright has introduced a bill to establish a Bureau of Scientific Research in the Department of Commerce, which he says is designed to afford a medium through which new inventions may be properly developed with federal aid and made available to small industry or individuals who may desire to enter business. He believes it will be helpful to returning war veterans. "There is a real need for the utilization of existing patents in the interest of the people," he said, "and to encourage the latent inventive possibilities of the nation, through the elimination of existing handicaps and encouragement of small industries to seek and use such ideas." He explained that the bureau would be authorized to procure the services of leading scientists, engineers, chemists and other professional experts, to provide small enterprises with the best possible research facilities. The bill proposes to promote in the national interest the fullest and speediest introduction of new technics in science and invention and in manufacturing, communication and other phases of productive activity; also to promote the maintenance of free enterprise by making available to small and medium size business concerns scientific and technical inventions, products and processes and to establish a central scientific and technical office to assure the maximum use of these.

Facilities for Psychoneurotic Veterans Termed Inadequate

Newspaper reviews of the facilities for psychoneurotic war veterans charge that the medical profession is not prepared to care for these patients. "A staggering need for the creation of psychiatric facilities for the care of the mentally disabled" is reported by the National Committee for Mental Hygiene, which reports that twenty-five states do not have one community clinic for psychiatric care and that there are "vast areas" without doctors trained for this work. In the United States only 139 hospitals and clinics are ready to treat mental casualties. Only 30 neuropsychiatric hospitals are operated by the Veterans Administration, which has resulted in overcrowding and lack of outpatient care, according to the committee. While the war has increased the number of mental patients—half a million veterans have been discharged for psychiatric reasons and another half million are expected before war's end—the number of doctors to treat them has been reduced. A congressional inquiry revealed that care of psychoneurotic veterans is inadequate in veterans' hospitals, although the number of patients is growing. The situation is said to pose a big problem for Gen. Omar Bradley when he takes over the Veterans Administration.

Tuberculosis Experts Testify at Kelley Hearing

Army, Navy, Selective Service and civilian tuberculosis experts were to testify today and tomorrow before the committee headed by Representative Augustine B. Kelley of Pennsylvania to study aid to the physically handicapped. Hearings were to be resumed in room 429 of the Old House Office Building. Those who testified today were Col. Esmond R. Long, chief consultant on tuberculosis, Office of the Surgeon General, U. S. Army; Dr. Louis E. Siltzbach, Committee for the Care of Jewish Tuberculous; Capt. Robert Duncan, commanding officer of the Bureau of Medicine and Surgery at Bethesda, Md., U. S. Navy; Mr. Holland Hudson, National Tuberculosis Association and National Rehabilitation Council; Lieutenant Colonel Coatsworth, Selective Service System; Dr. Herman E. Hilleboe, U. S. Public Health Service Tuberculosis Control Division; Mr. Edward Hockhauser, Committee on Care of Jewish Tuberculous, and Mr. Edward K. Funkhouser, District of Columbia Tuberculosis Association.

Liberated War Prisoners Recovering Quickly

American prisoners of war released from German prison camps are recovering quickly and completely from malnutrition caused by starvation, according to a study based on 275 severe cases at the 217th General Hospital in Paris, released by the Office of the Surgeon General, U. S. Army. Lieut. Col. Don C. Wakeman, chief of medical service of the hospital, said that "a survey was made to determine the average daily gain of weight in uncomplicated cases of malnutrition, and those who had lost more than 25 pounds gained an average of 1⅕ pounds a day during an average observation period of twenty-five days." In milder cases six feedings a day are given of a high caloric and high vitamin diet, with supplementary vitamin preparations for those showing specific vitamin deficiency states. In the more severe cases there was inability to tolerate a sufficient quantity of food to allow recovery through feeding alone, and intravenous solutions, common blood plasma and transfusions of whole blood were necessary to get patients into condition where food would be tolerated. X-rays of patients with nausea, vomiting, diarrhea and intolerance to food showed changes in functions of the intestine resembling those of sprue. Considerable improvement was noticeable in two weeks.

Judge Vinson's Point of View Regarding Taxation

The medical profession may not be in complete harmony with the views on taxation of Judge Fred M. Vinson, chosen by President Truman to be secretary of the treasury in succession to Henry Morgenthau. While he believes that excess profits taxes on business should be repealed immediately after Japan is whipped, and he would write postwar tax bills to encourage capital taking job-making risks, he also believes that the personal income tax base should be broad, with lower exemptions than at present. Mr. Vinson is the fourth man with congressional experience to be brought into the Truman cabinet. The others are Secretary of State James F. Byrnes, Secretary of Agriculture Anderson and Secretary of Labor Schwellenbach.

Red Cross Launches Drive for Hospital Workers

The American Red Cross seeks 750 qualified social workers and 600 recreation workers for immediate duty in military hospitals rapidly filling with sick and wounded servicemen from the Pacific and European theaters. With demobilization in Europe, the wounded are returning so fast that the Red Cross has had to expand its hospital program.

Medical Legislation

MEDICAL BILLS IN CONGRESS

Drugs

At the request of the administrator of the Federal Security Agency, S. 1217 was introduced July 2 by Senator George, Georgia, to provide for the free importation of substances, together with their containers and other articles in use at the time of importation for the protection or preservation thereof, entered or withdrawn from warehouse by or for the account of the board of trustees of the United States Pharmacopeial Convention, or the Council of the American Pharmaceutical Association, for use by or on behalf of that board or that council in connection with the establishment by that board or the Committee on National Formulary of standards for the manufacture or control of medicinal products.

Veterans Administration

Representative Rogers, Massachusetts, has introduced H. R. 3685, proposing that any veteran who as a result of service connected disability is so helpless as to be in need of a nurse or attendant shall be granted an allowance of $100 a month in addition to any pension or compensation to which he is otherwise entitled under laws administered by the Veterans Administration.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Prisoners Volunteer for Experiment with Bubonic Plague.—More than 100 San Quentin prisoners recently volunteered for the government's investigation of bubonic plague. Fifty selected men were inoculated with the new vaccine of the George Williams Hooper Foundation of the University of California under a research program sponsored by the Office of Scientific Research and Development, according to the San Francisco *Chronicle*.

Eric Liljencrantz Memorial.—The Hewlett Club of Stanford University School of Medicine has established the "Eric Liljencrantz Memorial Collection on Aviation Medicine" in the Lane Medical Library. Dr. Liljencrantz graduated at Stanford medical school in 1929 and was assistant professor of medicine (radiology) at the time he entered service. A bronze tablet commemorating the service and untimely death of Commander Liljencrantz has been set up at the Naval School of Aviation Medicine, U. S. Naval Air Station, Pensacola, Fla., where he lost his life in an airplane crash Nov. 5, 1942, while studying the physiologic effects of acceleration.

Diabetic Children's Camp Opens.—Camp Whitaker, said to be the only camp for diabetic children on the West Coast, will open for the eighth consecutive year from July 22 to August 19. The camp is under the direction of Dr. Mary B. Olney, assistant professor of pediatrics, University of California Medical School, San Francisco. It is located in the Sierras at an altitude of 5,600 feet, is 60 miles east of Fresno and adjoins the General Grant Grove section of Kings Canyon National Park. The camping period is divided into two periods of two weeks each at a cost of $35 each period plus transportation. There are several camp scholarships available. Applications should be made to Dr. Olney at the University of California, San Francisco.

GEORGIA

University News.—Dr. Edward J. McCormick, Toledo, Ohio, chairman of the Council on Medical Service and Public Relations, American Medical Association, gave the commencement address at the University of Georgia School of Medicine, Augusta, June 11, on the present trend in medical care.

Personal.—Dr. John H. Walker, Atlanta, has been appointed pediatric consultant to the division of maternal and child health of the Georgia Department of Public Health, succeeding Dr. Paul R. Ensign, who is now director of the maternal and child health division of the Kansas State Board of Health, Topeka (THE JOURNAL, April 21, p. 1066).——Dr. Rufus F. Payne, Atlanta, assistant health officer in Fulton County, has been appointed medical superintendent of the State Tuberculosis Sanatorium at Alto.——Dr. John M. Walton, Atlanta, has been named associate medical director of the Southeastern area of the American Red Cross.

ILLINOIS

Personal.—Dr. Willis I. Lewis, Herrin, was elected president of the Williamson County Health Council at its meeting May 14.——Dr. and Mrs. Emerson M. Brewer, Rantoul, observed their fiftieth wedding anniversary recently.

Chicago

Symposium on Forensic Medicine.—The committee on local medicolegal problems of the Institute of Medicine of Chicago, with assisting societies of physicians and lawyers, will hold a symposium on six Monday evenings beginning September 24 through October 29, the subjects selected being especially planned for pathologists, physicians, lawyers, toxicologists and others interested in forensic medicine. Each subject will be introduced with a formal discussion by a physician and a lawyer, followed by a panel discussion and question period. A complete program will be available later.

Industrial Health Committee.—The Chicago Industrial Health Committee is the name tentatively selected for an organization now being developed for Chicago and Cook County. The project is being formed to provide industrial workers in participating industries with continuous and authentic health information on vital health problems and to promote the utilization of procedures, such as Kahn tests, chest x-rays and vision testing, to be made available through cooperating health agencies as requested and available. The entire project will be set up as a health education program. The movement has been endorsed by the American Association of Industrial Physicians and Surgeons, the Council of Social Agencies of Chicago, the Chicago Medical Society and Chicago Health Department, the educational committee of the Illinois State Medical Society, the City of Chicago Municipal Tuberculosis Sanitarium, Chicago Dental Society, Chicago Society of Industrial Physicians and Surgeons, industrial hygiene division of the state department of public health, industrial nurses section of the Illinois State Nurses Association, the Cook County Public Health Unit and others. Efforts are now being made to obtain a full time executive secretary. Additional information may be obtained from Dr. Frederick W. Slobe, 2024 South Western Avenue.

Country Home for Convalescent Children Sold.—The University of Chicago has sold the property of the Country Home for Convalescent Children at Prince Crossing, near Wheaton, to Wheaton College, according to an announcement June 29. The Wheaton College Academy will be transferred in September to the new site and buildings, which will provide accommodations for 125 boarding and 75 commuting students. The sale reflects the fundamental changes in methods of treating crippled children since the Country Home was founded in 1914. While formerly the general method of treatment was largely by immobilization in casts, today bone and joint deformities and diseases are generally corrected or cured by surgery, with such relatively brief periods of convalescence that the number of patients in the Country Home has dwindled steadily. In a statement, Frederic C. Woodward, LL.D., chairman of the board of trustees of the Country Home, said that the changes in methods of handling orthopedic cases have so greatly reduced the time of convalescence that the home at no time in the past five years has operated at more than half of its bed capacity. In the last year occupancy has never risen above 20 per cent, making maintenance costly beyond all proportion to the benefits derived. There has also been a trend away from placing children in institutions, away from their family environment, he said; it is now considered better practice to keep the children at home as much as possible and provide medical care with a minimum of separation from the family. Transfer of the work to the campus will avoid further waste of charitable funds and ineffective use of medical personnel. The 18 patients now at the home will be transferred either to the University of Chicago clinics or to medical agencies from which they were referred to the home. The Country Home, founded by the late William J. Chalmers, of the Allis-Chalmers manufacturing firm, and his wife, became affiliated with the university in 1927 and was amalgamated in 1938. The several memorial funds which have sustained the home will be continued, with preservation of memorial tablets, under present plans, which call for the erection of a new building near the university within two years. This building will be established as a permanent memorial to Mr. and Mrs. Chalmers and will form part of the integrated medical center at the university, Mr. Woodward stated.

MASSACHUSETTS

License Changes.—The board of registration in medicine on June 6 took the following actions:

Dr. Julius Shubert, Boston, license revoked for not less than three years because of gross misconduct in the practice of his profession, as shown by collusion.

Dr. Pasquale E. Massa, Boston, license suspended for a period of one year because of gross misconduct in the practice of his profession, as shown by violation of the narcotic law and conspiracy to violate this law (THE JOURNAL, June 30, p. 679).

Dr. Ralph K. Coleman, Arlington, license restored to practice medicine in Massachusetts.

Medical Schools Combine in Commencement Exercises.—In the first ceremony of its kind, 292 recent medical and dental graduates of Harvard University, Tufts College and Boston University received army and navy commissions June 23 in combined exercises in the Harvard Medical School Quadrangle. The army commissions were awarded by Major General Sherman Miles, commanding the First Service Command, the Navy by Rear Admiral Felix Gyax, commandant of the First Naval District. Major General Norman T. Kirk, Surgeon General of the Army, gave the principal address. Other speakers were Leonard Carmichael, LL.D., president of Tufts, and James B. Conant, LL.D., president of Harvard. Daniel A. Marsh, LL.D., president of Boston, observed that the first combined exercises of the three schools of medicine demonstrated the spirit of cooperation in medical education.

MICHIGAN

Hardy Kemp Named Dean.—Lieut. Col. Hardy A. Kemp, M. C., secretary of the Army Medical Schc [illegible] has been appointed dean of the Wayne [illegible] Medicine, Detroit. Colonel Kemp graduat [illegible] versity School of Medicine in 1926 and prior to his entrance into the service was dean of the Ohio State University College of Medicine, Columbus, Ohio.

MISSISSIPPI

Personal.—Dr. Thomas K. Chandler Jr., Tunica, director of the Tunica County Health Department, has been appointed to a similar position in Coahoma County, succeeding Dr. Guy R. Post, who has become medical director of the crippled children's service and medical consultant of vocational rehabilitation for the state (THE JOURNAL, March 10, p. 606).——Dr. James P. Sharon, who has been acting director of the Marion County Health Department, Columbia, has resigned, effective May 15.

NEW JERSEY

Joseph Buch Dies.—Joseph G. Buch, director of the New Jersey Rehabilitation Commission and chairman of the state crippled children's commission, died at his home in Trenton, June 21, of coronary thrombosis, aged 63.

Special Society Election.—Dr. Harry J. Perlberg, Jersey City, was chosen president of the Radiological Society of New Jersey at its annual meeting May 16. Other officers include Drs. John L. Olpp, Englewood, vice president; Harry R. Brindle, Asbury Park, secretary, and William H. Seward, Orange, treasurer.

NEW YORK

Increased Fees in Relief Cases.—The Medical Society of the County of Erie was instrumental in having approved on June 14 an increase in fees for relief cases. The Erie County Board of Social Welfare voted the action, effective November 1, in conformance with the society's recommendations.

Prevalence of Rabies.—Quarantine of all dogs in Rochester and seven adjoining townships was put into force July 1 as a result of a certification of the existence of rabies issued June 26 by Dr. Edward S. Godfrey Jr., Albany, state commissioner of health, newspapers reported. Two cases of rabies in dogs reported within the week prompted the order. Positive diagnosis of rabies in a dog in Flushing, Queens, was formed by the New York City Department of Health, it was reported June 29, the first to be reported in the city since February and the first occurrence of the disease in the borough of Queens since August 1941.

New York City

Columbia to Receive Fund for Cancer Research.—On termination of a residuary trust set up under the will of Mrs. Edith Dunshee Converse, who died June 21, Columbia University will receive one half of the principal, the income to be used for the maintenance and equipment of a laboratory for research in the field of malignant diseases. The fund will be known as the "Edith Dunshee Converse Fund," newspapers report.

Student Prizes Awarded.—At the one hundred and ninety-first commencement of Columbia University, June 5, prizes to seniors included the Janeway prize to J. P. Cole for the highest marks in efficiency and ability. The Harold L. Meierhof Memorial Prize for the best work in pathology during the year went to George Lally Curran. Virginia C. Nichols was given the Dr. William Perry Watson prize in pediatrics, an award going to the student who has been in attendance on the regular course of instruction for at least two years and who has shown the most notable work in the study of the diseases of infants and children. Another feature of the commencement exercises included the presentation of the honorary degree of doctor of science to Edwin J. Cohn, Ph.D., professor of biochemistry, Harvard Medical School, Boston, and to Dr. Herbert S. Gasser, director of the Rockefeller Institute for Medical Research.

NORTH CAROLINA

David Young Named Superintendent of Mental Health.—Dr. David A. Young, assistant professor of psychiatry and neurology, University of Utah School of Medicine, Salt Lake City, has been appointed general superintendent of mental health for the four state hospitals of North Carolina, a newly created position. The appointment will be effective September 1. In making the selection, five candidates for the position were chosen to familiarize themselves with the position and, during the course of their study, their expenses were paid. The five considered were, in addition to Dr. Young, Colonel Lloyd J. Thompson, M. C., Lieut. Col. Walter E. Barton, M. C., Lieut. Col. Malcolm J. Farrell and Dr. Gaylord P. Coon, Boston. The new superintendent is to coordinate the work of the four state institutions in order that better medical and mental care may be available. The position was authorized by the 1943 general assembly and never filled. It was, however, given new emphasis by the 1945 assembly, which also set up a new hospitals board of control (THE JOURNAL, June 16, p. 532). The governor, following his appointments to the new board, also appointed a twelve man advisory commission to assist the board with Dr. Hubert B. Haywood, Raleigh, as chairman. The proposed program of better care includes a plan to buy a post hospital at Camp Sutton, Monroe, from the United States government, since it has been abandoned by the army. This, if carried out, will be used to take care of about 1,000 of the senile arteriosclerotic group in the other hospitals, freeing beds for the care of patients for whom there may be some hope of a cure.

OHIO

Fifty Years of Practice.—Physicians who have recently completed fifty years in the practice of medicine include Drs. Samuel L. Bernstein, Cleveland; Albert J. Bausman, Piqua, and Dr. Frank B. Gregg, Wellington.

Graduate Training for Returning Veterans.—On July 1 the Ohio State University College of Medicine, Columbus, launched a plan for postgraduate training designed primarily for returning veterans and other physicians who may wish to participate. Those who take the course will be required to spend full time in the university hospital or affiliated institutions of the medical school for a period of not less than two weeks nor longer than three months and will be under the immediate supervision of one of the members of the faculty whom they shall select and who shall serve as a counselor. Additional information may be obtained from Dr. Bruce K. Wiseman, Kinsman Hall, Ohio State University, Columbus 10.

Charles McKhann Named Professor of Pediatrics at Western Reserve.—Dr. Charles F. McKhann, assistant to the president in charge of research, Parke, Davis & Company, Detroit, has been named professor of pediatrics at Western Reserve University School of Medicine and director of pediatrics at University Hospitals, Cleveland. He succeeds Dr. Henry J. Gerstenberger as professor of pediatrics at Western Reserve and director of Babies and Childrens and Rainbow hospitals. Dr. Gerstenberger will become professor emeritus of pediatrics beginning with the next school year. The appointment became effective as of July 1, but Dr. John A. Toomey will remain as acting director of University Hospitals until September 1 and will also continue as professor of clinical pediatrics and contagious diseases at the school of medicine and in charge of the departments of contagious diseases at the university and city hospitals. Dr. Toomey was appointed acting director of pediatrics at University Hospitals when Dr. Gerstenberger was granted a leave of absence in July 1944 to devote most of his time during the next five or six years preparing a mass of clinical and scientific data for publication and writing a history of the Babies and Childrens Hospital and its predecessors (THE JOURNAL, Aug. 19, 1944, p. 1152). Dr. McKhann graduated at the University of Cincinnati College of Medicine in 1923. He served in various capacities at Harvard Medical School, Boston, and the Harvard School of Public Health from 1923 to 1940, when he went to the University of Michigan Medical School, Ann Arbor, as professor of pediatrics and communicable diseases. For a year in 1935 he was visiting professor of pediatrics at Peiping Union Medical College on a grant from the Rockefeller Foundation.

OKLAHOMA

Public Relations Program Approved.—The Oklahoma State Medical Association has activated a public relations program encompassing public and postgraduate education, postwar planning and plans to foster closer unity of county medical societies. The project designed for public education will use the press, radio, motion pictures and public speakers to present the importance of scientific medicine to the public. Postgraduate activities will include cooperation with a project now under consideration by the University of Oklahoma School of Medicine, Oklahoma City. The state department of public health and the state association will cooperate in the postwar program

to be of benefit of doctors returning from service. The interest of the state association in its county medical societies will be continued, and service will be expanded to assist the local units in carrying out service to the public.

New Board of Health Formed.—On June 15 the governor appointed the new nine member state board of health, created under the recently enacted house bill number 77, which stipulated that the new board be composed of a representative from each congressional district and one from the state at large, five to be members of the Oklahoma State Medical Association. The board members are:

Dr. Charles R. Rountree, Oklahoma City, board member at large, nine year term.
A. G. Reed, osteopath, Tulsa, first district, six year term.
Dr. Charles Edgar White, Muskogee, second district, five year term.
Dr. Tracey H. McCarley, McAlester, third district, three year term.
Dr. Catherine F. T. Brydia, Ada, fourth district, one year term.
Mr. Bert Loy, hospital administrator, Oklahoma City, fifth district, seven year term.
Mr. William F. Schumacher, engineer, Lawton, sixth district, two year term.
Dr. Victor C. Tisdal, Elk City, seventh district, eight year term.
Fred Seids, D.D.S., Perry, eighth district, four year term.

Officers are Dr. Rountree, chairman, Dr. White, vice chairman and Mr. Loy, secretary. At the organization meeting, June 22, Dr. Grady F. Mathews, Oklahoma City, was unanimously voted to continue as state health commissioner.

PENNSYLVANIA

District Meetings.—The annual meeting of the Eighth Councilor District of the Medical Society of the State of Pennsylvania met June 27 in Meadville. Among the speakers were Drs. Bernard Fisher, Pittsburgh, on "Penicillin vs. Sulfonamide Therapy—A Clinical Evaluation" and William Bates, Philadelphia, "Early Diagnosis of Carcinoma of the Rectum." Drs. Thomas O. Glenn, Bradford, and Franklin G. Haines, Warren, were presented with testimonials in recognition of their completion of fifty years in the practice of medicine. The Ninth Councilor District held its annual meeting in Punxsutawney June 28. Addresses were given by Dr. Fisher, Dr. John P. Henry, Pittsburgh, on "Thrombophlebitis: Its Modern Treatment" and Dr. Charles J. Barone, Pittsburgh, "Obstetrics in General Practice." Members honored for their completion of fifty years in the practice of medicine were Drs. Joseph J. Schultis, Butler; Howard B. Buterbaugh, Indiana; William A. Simpson, Indiana; Harry B. King, Reynoldsville, and Rose M. Dunn, Franklin.

Philadelphia

Alexander Wiener Receives Alvarenga Prize.—On July 14 the College of Physicians of Philadelphia is awarding the Alvarenga Prize to Dr. Alexander S. Wiener, serologist to the office of chief medical examiner of New York City, in recognition of his work on the various types of Rh factors and on their genetic transmission. On October 3 Dr. Wiener will give the Alvarenga Lecture before the college and the Philadelphia County Medical Society on "Rh Blood Factors in Clinical Medicine." The Alvarenga Prize was established by the will of Pedro Francisco deCosta Alvarenga, Lisbon, Portugal, an associate fellow of the college of physicians, "to be awarded annually by the college of physicians on each anniversary of the death of the testator, July 14, 1883." The college usually makes this award for significant published work and invites the recipient to deliver an Alvarenga Lecture before the college.

TENNESSEE

Dr. Burch Retires.—Dr. Lucius E. Burch on July 1 retired as professor and chairman of the department of obstetrics and gynecology at the Vanderbilt University School of Medicine, Nashville. Dr. Burch, who graduated at Vanderbilt in 1896, joined the faculty in 1902 as professor of gynecology. He was dean of the school from 1914 until he retired to become head of the department of obstetrics and gynecology.

PUERTO RICO

Status of Veterans Facilities.—Dr. Jaime Serra Chavarry, head of the insular office of the veterans administration in San Juan, left for Washington recently to confer with General Omar N. Bradley, newly appointed veterans administrator, on plans for the expansion of the veterans administration in Puerto Rico and possibly will urge that the federal government build a veterans' hospital on the island, it is reported. Under the present setup veterans are hospitalized by the administration in private clinics and hospitals, which receive payment from the federal government. These clinics and hospitals, numbering fourteen in all, have 1,000 beds available for veterans and a minimum of 100 beds for emergency cases at all times, which is considered insufficient for the large number of veterans that will return to this island after final defeat of the Japanese. The construction of a veterans hospital in Puerto Rico, however, would release 1,100 beds to the general public, in addition to providing the type of care and attention that federal supervision would guarantee. Present arrangements are inadequate. Simultaneously, the increase in requirements for the general public in island hospitals will add in the next three or four years to the burden of providing proper hospitalization and medical attention for the population.

GENERAL

Journal Honors Physicians.—A recent issue of the *Review of Gastroenterology* was dedicated to Drs. Samuel Weiss, New York, and Charles W. McClure, Boston, in honor of their sixtieth birthdays. Dr. Weiss has been editor of the *Review* since March 1934. Dr. McClure is a charter member of the National Gastroenterological Association and helped to organize the Boston chapter, of which he is secretary-treasurer.

Quinacrine Again Under Allocation Control.—Because of increased American and allied military requirements for quinacrine, popularly called atabrine, in line with the redeployment of troops to the Pacific areas, the War Production Board June 19 placed the chemical under allocation control of schedule III of order M-300, the general chemicals allocation order. Quinacrine, used for the treatment of malaria, was originally placed under allocation in April 1943, when increased military requirements for the chemical, to be used as a substitute for quinine, made the available supply inadequate to meet demands. However, lessened military demands later in the war made it possible to remove allocation controls in January of this year. It will be necessary to increase production of the drug in order to meet all requirements fully. With controlled distribution, adequate supplies of quinacrine will be assured for civilian use in malarial regions of the United States.

Form Corps of Poliomyelitis Emergency Volunteers.—The National Foundation for Infantile Paralysis is organizing a nationwide program to form and train a corps of poliomyelitis emergency volunteers to assist physicians, physical therapists and nurses in areas where infantile paralysis epidemics occur. The new corps will be called "PEVS." The initial phases of the program provide only for instruction in those areas where qualified teaching personnel, institutional facilities for the care of poliomyelitis victims and actual infantile paralysis cases exist or are anticipated during the coming year. If an outbreak occurs in an area where the volunteers have not been organized and trained, the foundation will be prepared to give emergency training assistance through emergency courses. The course, designed for eight lecture and demonstration classes of two hours each, will be scheduled for local convenience. The volunteers will be organized through the women's committees in charge of Miss Elaine Whitelaw, director of women's activities of the national foundation.

Social and Environmental Factors in Medicine.—The Milbank Memorial Fund has given a grant to finance a study by the Association of American Medical Colleges in cooperation with the American Association of Medical Social Workers on the teaching of the social and environmental factors in medicine. A committee of twenty-five physicians and medical social workers who are engaged in this teaching has been formed to direct the study, under the name of the Joint Committee on the Teaching of the Social and Environmental Factors in Medicine. The co-chairmen are Dr. Jean A. Curran, dean, Long Island College of Medicine, Brooklyn, and Miss Eleanor E. Cockerill, associate professor of social case work at the School of Applied Social Sciences, University of Pittsburgh. A centrally located project subcommittee has been set up under the chairmanship of Dr. Jonathan E. Rhoads, assistant professor of surgical research and acting director of the Harrison Department of Surgical Research, University of Pennsylvania School of Medicine, Philadelphia. The executive secretary of the study is Miss Harriett M. Bartlett, 49 Fruit Street, Boston 14. It is the aim of the study to bring together and analyze the experience of the group of medical schools in introducing students to the social and environmental components in medicine. Visits to selected centers will be made by members of the committee. The study is expected to last through 1945, at the end of which time a report summarizing the findings will be prepared.

Blue Cross Opens National Enrolment Office.—To assist in the enrolment of employees of national firms with plants or branch offices located in areas served by two or more Blue Cross hospital and medical prepayment organizations, the Blue Cross Plans of the United States will open a national enrolment office on July 16 in New York. The enrolment office will be an activity of the American Hospital Association's [illegible]

pital service plan commission, which coordinates the program of the Blue Cross Plans serving forty-three states, seven Canadian provinces and Puerto Rico, Clarence Rufus Rorem, Ph.D., Chicago, director, said in making the announcement. Headquarters of the national enrolment office will be located at 370 Lexington Avenue, room 1014, New York. The enrolment director will be Frank Van Dyk, who has served the New York City Blue Cross Plan for the past ten years and who will continue as vice president in charge of enrolment for Associated Hospital Service of New York in addition to his new duties. Mr. Van Dyk will represent the various Blue Cross Plans in their presentation of a uniform program to national firms, but each local state and community organization will conduct the actual enrolment and pay hospital bills for the local employees of a national firm or organization. As a further encouragement to national enrolment, the Blue Cross Plans have agreed to enroll the branch office or branch store employees of a national firm even though the number of employees may not meet the minimum group requirements of the enrolling plan. Blue Cross Plans have agreed also to accept transfers of membership when the employee of a nationally enrolled firm moves. Transfer of membership of the employee's family is also included.

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the week ended June 30 have been received from the division of public health methods, U. S. Public Health Service, as follows:

LATIN AMERICA

Health Activities in Latin America.—*Visitors to the United States.*—Dr. Manuel Picco, Buenos Aires, Argentina, is to specialize in orthopedics at the Lahey Clinic, Boston, on a travel grant awarded by the Institute of Inter-American Affairs.——Dr. Victor Grossi, chief of the public health office of Valparaiso, Chile, has gone to the United States to carry on a tour of health and sanitation programs in several states.

Society News.—Dr. Dante Pazzanese has been chosen president of the newly created Sociedade Brasileira de Cardiologia, with headquarters in Campinas, São Paulo, Brazil. Other officers include Drs. Adriano de Azevedo Pondé, vice president, and Jose de Proenca Pinto de Moura, secretary. Dr. Leovigildo Mendonca de Barros is editor of the *Arquivos de Cardiologia*, the official journal of the society.

Personal.—Dr. Peter A. Clearkin, government bacteriologist of British Guiana, recently was the recipient of a decoration from King George VI of England for his work in 1944.——Dr. Antonio Peña Chavarria, director of the Hospital San Juan De Dios, San José, Costa Rica, has been granted a fellowship from the John and Mary R. Markle Foundation, through the Association of American Medical Colleges, according to *Tropical Medicine News*. It was to become effective early in May and will be utilized in visits to various medical centers in the United States. The fellowship was granted Dr. Peña in recognition of the great services rendered by him to instructors from medical schools of the United States and Canada, who for the last eighteen months have been gaining practical experience in tropical medicine in San José under his direction.——Eric G. Ball, Ph.D., associate professor of physiologic chemistry at Harvard Medical School, Boston, is giving a series of lectures at the School of Medicine of the University of Brazil in Rio de Janeiro, where he will direct research in cellular respiration, according to *Science*. His trip is under the joint auspices of the Brazilian government and the department of state of the United States.——Brig. Gen. Henry C. Dooling, M. C., who was on a thirty day mission in the battle areas of the Mediterranean theater, has returned to his activities as chief health officer of the Panama Canal. While in Italy, General Dooling met Major Gen. Morrison C. Stayer, M. C., who preceded him as chief health officer of the Panama Canal. Col. Albert R. Dreisbach, M. C., acted as chief in General Dooling's absence.

Division of Child Welfare in Rio Branco.—A division of child welfare has been recently established in the territory of Rio Branco, Brazil, according to the *Child*. This division will engage in preventive and curative work under the general supervision of the National Children's Bureau in Rio de Janeiro. The present plans provide for medical and dental care and improvement of nutrition for all children and youth in the municipalities. The territory has been divided into fifteen districts, in each of which will be established a maternity home, a milk station for children, a day nursery and a kindergarten.

Smallpox Vaccination of Civilian Residents.—On June 1 the health department of the Panama Canal started smallpox vaccination of about 300,000 civilian residents in the Canal Zone and the cities of Panama and Colon. Authority for the undertaking is derived from board of health ordinance number 5, approved in 1915, which provides that all persons living in these communities must submit to the vaccinations at intervals of not more than five years. A similar campaign was conducted in 1940.

Argentina's Plan for Health.—The National Health Department, an agency of the Ministry of the Interior, which is said to dominate unrestrictedly the health and sanitation activities in Argentina, proposes, through a national sanitary plan and enforcement measures now being formulated, to carry on an intensive drive against cancer, cholera, bubonic plague, heart diseases, pneumonia, yellow fever, smallpox, exanthematous typhoid, diphtheria, mumps, scarlatina, whooping cough, lethargic or epidemic encephalitis, infantile paralysis, grip, tuberculosis, leprosy, rabies and trachoma.

Conference on Tropical Dermatology.—A course on tropical dermatology will be conducted in Mexico City August 6-18 under the direction of Dr. Fernando Latapi, professor of dermatology, Universidad Nacional Facultad de Medicina, Mexico, D. F., and with the cooperation of Secretaria de Salubridad y Asistencia Publica. Applications to take the course should be sent to Dr. Latapi, Zacatecas 220-6 Mexico, D. F., Mexico. Additional information may be obtained from Dr. Leon Goldman, University of Cincinnati College of Medicine, Cincinnati 1. The program, prepared at the request of Dr. Howard Fox, New York, has been made up especially for American dermatologists and will include a summary of general information, the presentation of clinical cases and laboratory demonstrations, such as bacteriology, parasitology, mycology and histopathology:

Dr. Jesus Gonzalez Urueña, Tropical Characteristics of Mexican Dermatology.
Dr. Salvador Gonzalez Herrejón, Pinta
Dr. Manuel Martinez Baez, Onchocerciasis
Dr. Julio Bejarano, Syphilis
Dr. Latapi, Leprosy.
Dr. Antoni[illegible] d Tinea Capitis.
Dr. Jorge [illegible] s
Dr. Oswal[illegible] Venereum.

FOREIGN

Personal.—Dr. John A. Nixon, Bristol, was appointed Dr. Alexander Black lecturer for 1945 for the Royal College of Physicians of Edinburgh.

National Institute of Physiology in China.—*Science* reports that equipment for a National Institute of Physiology in China, devoted entirely to the study of developmental physiology, is now being purchased in the United States by the future director of the institute, Dr. Shu Chu Shen, who is working in the Highpolymer Research Bureau of the Polytechnic Institute of Brooklyn. Dr. Shen is in the United States as a representative of the ministry of education of the Chinese government. It is planned to establish the institute in Shanghai after the war, since it is advisable to have it near a seaport. One of the first projects will be the investigation of the nutritional status of Chinese children with a view to improving the content of foods with essential minerals and vitamins.

LONDON

(From Our Regular Correspondent)

June 9, 1945.

The Treatment of Advanced Starvation

The conditions in German prison camps and in occupied countries have brought to the front the problem of the treatment of advanced starvation. At the Royal Society of Medicine Dr. H. E. Magee opened a discussion on this subject, particularly on the use of protein hydrolysates. He worked for several years on the physiology of absorption and found that as fasting continues there is a progressive diminution in the absorptive powers and protective functions of the intestinal mucosa. The columnar epithelium is progressively disorganized, exposing the intestine to irritation by undigested foods with resultant diarrhea. Parenteral feeding, by injection of amino acids to reconstruct the mucosa, is indicated. These should be used by the body as building materials but in starvation are apt to be broken down and used for energy. To protect them it is necessary to give glucose and B vitamins, which enable the body to metabolize glucose.

Dr. Hugh S. Stannus said that the conditions in starvation for which protein hydrolysate therapy had been introduced made a complex picture of many unknowns. If the patient could swallow, digest and absorb the requisite protein, this might be supplied in some suitable form, such as reconstituted dried skim milk powder by mouth or, if he could not swallow, by nasal tube feeding. But if he was unable to digest, protein hydrolysate should be given by mouth or by gavage and if he could not swallow, digest or absorb, resort must be made to intravenous administration. But this conception had been shaken by the case of a repatriated prisoner in the last stages of starvation who had difficulty in taking his milk diet. The case seemed to demand intravenous hydrolysates, but none were available. He was therefore given glucose-saline intravenous therapy, a crude liver extract parenterally and teaspoon feeding with powdered liver extract. The response was dramatic, and the same result was obtained in another case.

Dr. Janet Vaughan, who was one of a small team sent out by the Medical Research Council to test the various methods of feeding in the Belsen camp, described the horrible conditions she found there. She first discussed intravenous therapy. Five patients were given amigen, which they took well, with no reaction. Four did well, but the fifth showed no improvement. The workers had no doubt that for intravenous therapy serum was preferable to hydrolysates. The explanation was that with it there was much more protein and relatively little fluid.

Mass Radiography in the Early Detection of Pulmonary Tuberculosis

The Medical Research Council has published a report on the results obtained by mass miniature radiography in the early detection of tuberculosis of the lungs. A survey of 23,000 persons from two factories, a large office group and a mental hospital, all in greater London, was conducted. Leaving out the mental hospital, because tuberculosis has long been known to show a higher incidence than the average in such institutions, interest centers on the early detection of disease among the general working population. The figures for the two factories and the office group were similar: between 1 and 1.5 per cent newly discovered tuberculous lesions. About a fourth of the persons affected were advised to leave work immediately for institutional treatment. The rest required outpatient observation while remaining at work. If the persons examined can be taken as a fair sample for the rest of the country, these figures mean an immediate temporary loss of 3 or 4 per thousand and some adjustment of work of 10 per thousand remaining under supervision. The final diagnosis was not made on a miniature film alone. About 6 per cent of persons were asked to return for a full size film and about 2.5 per cent for a medical interview.

Two Benefactors of Blinded Prisoners of War in Germany

Major Charteris, the Liverpool ophthalmic surgeon who twice declined repatriation in order to continue his treatment of men in German prison camps, was welcomed at a luncheon in London, which was presided over by Sir Ian Fraser, chairman of St. Dunstan's (the institute for blinded soldiers and sailors). Major Charteris was captured in Greece in 1940 and sent to Germany, where his captors soon recognized his skill in treating eye casualties. Twenty-five blind ex-prisoners of war, escorted by their wives or fiancées, were present at the luncheon. Another benefactor of the blinded prisoners, Lord Normanby, also was thanked. He was severely wounded, though not blinded, in the battle of France and while in a German hospital became interested in the blinded prisoners there. He taught himself braille from a book he found in a salvage dump and then instructed blinded soldiers how to read, thus establishing the camp instructional school, which developed with the help of materials sent by the British Red Cross.

BRAZIL

(From Our Regular Correspondent)

SÃO PAULO, May 28, 1945.

Campaign Against Trachoma

Besides the state of São Paulo, the third most important focus of trachoma in Brazil, where there is a special service of the state health department to combat the disease, two important areas of the highest prevalence of trachoma exist in Ceará, a northern state, and in Paraná, a southern state, where the efforts against that scourge have not yet been organized on a practical basis. In some districts of the state of Paraná a previous survey of a good sample of the population disclosed that an average of 10 per cent of the school children and 30 per cent of the adult rural population presented the disease. For this reason the National Department of Health has founded in the latter two states, in cooperation with the local authorities, several centers of treatment and control of the disease under the supervision of Dr. Herminio B. Conde, an able ophthalmologist with an extensive knowledge of the problem of trachoma. Some particular data are now available concerning the antitrachoma work during the first quarter of this year. Of 23,144 persons examined, 1,288 new cases have been discovered, for which 10,519 dressings and 20,866 instillations of collyria have been done, and 26,815 tablets of sulfonamide preparations have been distributed. Clinical cure was obtained in 221 cases. Among these trachomatous persons an average of 2 per cent were blind in both eyes, 6 per cent were blind in one eye, 29 per cent had lost 5/10 of the ocular acuity, 37 per cent had lost 3/10 of the acuity and 26 per cent had normal vision. This month a new survey is just beginning which will cover the great valley of the São Francisco river, which flows from the south to north through central Brazil and is the axis of large migrations of population that link the northern and the southern areas of high prevalence of trachoma.

Prolapses of the Uterus and Cancer

All medical publications agree in finding exceptional the association between prolapse and cancer of the cervix of the uterus. Recently Dr. Licinio Dutra published a paper including 3 well documented cases with another 5 cases taken from Brazilian gynecologists. After reviewing the different theories which have been formulated to explain the coincidence of these

two disorders Dr. Licinio Dutra draws the following conclusions: "The poor blood and lymph circulation associated with uterovaginal prolapse, the atrophy of the mucous membrane and of the endocervical and endometrial glands and the rarity of inflammatory manifestations of the irritative type might explain why uterine prolapse and cervical cancer so seldom coincide, together with the excessive cornification and the altered epithelium of the mucous membrane of the cervix and vagina, which reduce the possibility of cancer in uterine prolapse."

Brazilian Oranges

Much research is being aided by grants from the Fundos Universitários de Pesquisas para a Defesa Nacional. Experiments have been performed at the Department of Physiology of the Faculdade de Medicina de São Paulo by Prof. Franklin de Moura Campos to study the nutritive value of certain varieties of Brazilian oranges. It was found that Brazilian oranges are poor in calcium salts. Ascorbic acid and thiamine were found in large amounts. Ascorbic acid was determined by a photoelectric colorimeter (Klett-Sumerson) and vitamin B_1 by the rat growth method devised by Miller.

The following conclusions may be drawn from Professor Moura Campos's investigations:

1. Brazilian oranges are poor in calcium salts, 0.016 Gm. per hundred grams being found on the average.

2. Some Brazilian oranges (Lima, Pera) are rich in ascorbic acid. Lima oranges presented an average of 55.48 mg. per hundred grams, Pera oranges 31.22 mg. per hundred grams.

3. Seleta and Pera oranges are rich in vitamin B_1. Both are given as the only source of thiamine that either prevented or cured beriberi.

4. Daily doses of 1 cc. of Seleta orange juice showed preventive action; doses of 2 cc. cured vitamin B_1 deficient animals.

5. Pera orange juice also was active.

Death of Dr. Adolph Lindenberg

Dr. Adolph Lindenberg, a leading dermatologist of São Paulo and a great figure of Brazilian medicine, died recently at an advanced age. Dr. Lindenberg was the founder of modern dermatology in São Paulo. He was a true representative of the great period of parasitologic investigation in dermatology, in which he became famous in Brazil as well as in all South America. Beginning with the first parasitologic identification of leishmaniasis in Brazil in 1909, he made in 1911 extensive researches on the subject of sporotrichosis, then a new disease described for the first time by A. Lutz in Brazil. The careful study of a patient affected with a mycetoma of the knee led Lindenberg to discover a new species of Actinomyces—Discomyces brasiliensis. He was one of the pioneers of the idea of the extraordinary clinical polymorphism of neotropical blastomycosis. One of the last subjects that interested Dr. Lindenberg in his parasitologic investigations in dermatology was pemphigus foliaceus ("wild fire"), the cause of which is still an engima. Among the several distinguished disciples of the dermatologic school which Lindenberg created in São Paulo are Dr. A. Martins de Castro and Dr. N. Rossetti.

Brief Items

Dr. Eurico Rangel, director of the Statistical Division of the Serviço de Biometria Medica, died recently at the age of 59. Dr. Rangel studied medical biometry and statistics at the School of Hygiene and Public Health of the Johns Hopkins University in 1925-1926 and was director of the Vital Statistics Bureau of the National Department of Health at Rio de Janeiro from 1933 to 1940.

On June 18-21 the annual meeting of the Brazilian Heart Association will be held. The medicosocial care of cardiac patients, the functional recuperation of such patients and neurocirculatory asthenia are the principal topics to be discussed. The organization committee includes Drs. Genival Londres and Oscar Ferreira Jr. of Rio de Janeiro and Drs. Dante Pazzanese and L. Mendonça Barros of São Paulo.

Drs. Guilherme M. Hautz, Raymundo B. Menezes and Wilson G. Santiago have been appointed professors of the Brazilian Army Medical School.

A modern hospital has been inaugurated in the state of Minas Gerais at Rio Preto (population 18,000). The fund for the erection of the hospital and for its maintenance has been raised from the population of the small city and the neighboring country.

The annual meeting of the Brazilian Association of Dermatology and Syphilography will be held at Belo Horizonte, state of Minas Gerais, on September 24-26. The principal subjects to be discussed are blastomycosis and the modern treatment of syphilis.

Dr. Alvaro Bahia, director of the division of child hygiene of the department of health of the city of Salvador, state of Bahia, left a few days ago for the United States, where he will study some organizations devoted to child welfare.

Dr. J. P. Azevedo Sodré, surgeon of the Municipal Emergency Hospital of Rio de Janeiro, has been elected a member of the National Academy of Medicine.

Marriages

WILLIAM BOYKIN LYLES JR., Spartanburg, S. C., to Miss Barbara S. Spencer of Dursley, Gloucestershire, England, March 28.

DAVID A. CLEVELAND, Milwaukee, to Mrs. Mary Macklin Stephens of Beverly Hills, Calif., in Riverside, Calif., February 26.

CHARLES AUGUST RENTROP JR., Germantown, Tenn., to Miss Marion Henrietta Meyn of Wallkill, N. Y., in Newburgh, N. Y., June 2.

MORRIS RAPPAPORT, Ellenville, N. Y., to Miss Judith Helen Preminger of Perth Amboy, N. J., March 18.

HENRY RANDALL THOMAS, Montgomery, Ala., to Miss Patricia Jane Piper of Rochester, Minn., May 26.

ROSS SIMONTON MCELWEE JR., Statesville, N. C., to Miss Doris Edgar in Kingston, N. Y., June 2.

NEWELL JEROME GRIFFITH, Tuckahoe, N. Y., to Miss Florrie Margaret Collins of Perry, Fla., June 2.

LOGAN UNDERWOOD MEWHINNEY, Holland, Texas, to Dr. RUTH ISADORA ALLEN of Dallas in May.

ALBERT F. TATUM, Tuscaloosa, Ala., to Miss Mary Nell Routledge of Birmingham, May 18.

HERBERT WINSTON FROSTICK to Miss Jean Caroline Wall, both of Charlotte, N. C., recently.

ROBERT J. ATWELL, Chillicothe, Ohio, to Miss Paula Mozelle Mitchell in Dayton, April 28.

HOWARD J. OHL, Lordsburg, N. M., to Miss Mary C. Shores of Union Star, Mo., April 3.

DOUGLAS T. LINDSAY, Minneapolis, to Miss Nelda Kanne of Faribault, Minn., March 26.

MILTON SALASKY, Norfolk, Va., to Miss Shirley Greenberg of San Francisco, May 19.

MACK RAYBURN to Mrs. Virginia Wilson Elam, both of Owensboro, Ky., April 6.

LORIN L. FOWLER, Marion, Ill., to Mrs. Lulu Caplinger of Downey, Calif., May 4.

MICHAEL J. LARKIN to Miss Helen M. Carroll, both of Trenton, N. J., June 20.

MANSON MEADS to Dr. HELEN WHEELER BELDING, both of Boston, May 26.

MARTIN SCHWEITZER to Miss Dorothy R. Chess, both of New York, June 9.

IRVING M. GREENBERGER to Miss Letty London, both of New York, June 3.

Deaths

William Hans Henry August Vogt ⊕ St. Louis; Missouri Medical College, St. Louis, 1897; joined the faculty of St. Louis University School of Medicine as instructor in gynecology and obstetrics in 1919, holding that position until 1924; assistant professor from 1924 to 1929 and associate professor from 1929 to 1933, when he became professor of gynecology and obstetrics and director of the department; instructor in gynecology and obstetrics at the Washington University School of Medicine from 1910 to 1915; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; member of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons, Southern Medical Association and the Central Association of Obstetricians and Gynecologists; past president of St. Louis Medical Society; served at various times on the gynecologic and obstetric staffs of Lutheran Hospital, City Sanitarium, City Infirmary, St. Louis Maternity, St. Luke's, St. John's and St. Louis City hospitals, St. Mary's Group of Hospitals and Deaconess Hospital and Home; since 1933 member of the advisory staff of St. Mary's Infirmary; died in Atlantic City, N. J., June 17, aged 68, of coronary thrombosis.

Henry Joseph Frederick Wallhauser ⊕ Mount Bethel, Pa.; University of the City of New York Medical Department, 1888; specialist certified by the American Board of Dermatology and Syphilology; past president of the Essex County (N. J.) Medical Society; member of the New Jersey Dermatological and Manhattan Dermatological societies; formerly medical director of Newark City Dispensary; consulting dermatologist to the Mountainside Hospital, Montclair, N, J., Overlook Hospital, Summit, N. J., Essex County Hospital for Contagious Diseases, Belleville, N. J., St. Mary's Hospital, Orange, N. J., and Lutheran Memorial Hospital, Crippled Children's Hospital, Babies' Hospital, Presbyterian Hospital, Newark City Hospital and the Hospital of St. Barnabas and for Women and Children, Newark, N. J., where he died May 5, aged 80, of arteriosclerosis and myocardial degeneration.

Oscar Francis Cox, Brookline, Mass.; Tufts College Medical School, Boston, 1914; professor of clinical urology at his alma mater and associate professor of medicine at the Boston University School of Medicine; served overseas during World War I; member of the subcommittee on venereal diseases of the National Research Council; secretary of the American Neisserian Medical Society; member of the American Medical Association; a director of the Massachusetts Society for Social Hygiene; director of the division of genitourinary diseases at the Massachusetts Memorial Hospital, Boston; chief of the genitourinary clinic of the Boston Dispensary; chairman of the advisory committee on venereal disease control of the Massachusetts Department of Public Health; died June 3, aged 57, of primary carcinoma of the lung.

John Pascal Sawyer, Cleveland Heights, Ohio; Western Reserve University Medical Department, Cleveland, 1886; since 1932 professor emeritus of therapeutics and clinical medicine at his alma mater, where he had served on the faculty in various capacities for many years; specialist certified by the American Board of Internal Medicine; member of the American Medical Association, American Gastro-Enterological Association and the Cleveland Academy of Medicine; fellow of the American College of Physicians; a trustee of the Cleveland Medical Library Association; emeritus chief of staff at St. Vincent Charity Hospital, Cleveland, where he died June 17, aged 83, of perforated stomach ulcer and terminal pneumonia.

Harold Glen Stevenson, Utica, N. Y.; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1920; on the staff of the Oneida County Tuberculosis Sanatorium (Broadacres); at one time superintendent of the Berks County Sanatorium in Reading, Pa.; formerly on the staffs of the Eagleville Sanatorium for Consumptives, Eagleville, Pa., Montgomery Sanatorium, Amsterdam, Pennsylvania State Sanatorium, South Mountain, Niagara Sanatorium in Lockport, Loomis Sanatorium, Loomis, and the Neversink Sanatorium, Reading, Pa.; died May 4, aged 49, of chronic arthritis and myocardial failure.

George Ollie Allen, Marietta, Ga.; Southern Medical College, Atlanta, 1893; member of the American Medical Association; past president of the Cobb County Medical Society; served during World War I; while a resident of Fargo served as physician and surgeon for the Southern Railway Company; on the staff of the Marietta Hospital; member of the Marietta Rotary Club; died May 26, aged 73, of coronary thrombosis.

John Andrews, Grant City, Mo.; Rush Medical College, Chicago, 1892; on the courtesy staff of the Missouri Methodist Hospital, St. Joseph, where he died May 16, aged 79, of hypertensive and arteriosclerotic heart disease.

Guy Frank Arnold, Washington, D. C.; Baltimore Medical College, 1900; died May 26, aged 68, of gastric hemorrhage and cerebral thrombosis.

Mary Lantz Austin, Gallipolis, Ohio; Ohio Medical University, Columbus, 1904; for many years on the staff of the Ohio Hospital for Epileptics; died in the Holzer Hospital May 21, aged 78, of cerebral and generalized arteriosclerosis and chronic arthritis.

Clarence H. Barber, Grand Rapids, Mich.; the Hahnemann Medical College and Hospital, Chicago, 1891; member of the American Medical Association; on the staff of the Michigan Veterans' Facility, where he died May 18, aged 75, of coronary thrombosis and pulmonary edema.

Arthur J. Behrendt, Chicago; College of Physicians and Surgeons of Chicago, 1891; emeritus member of the Illinois State Medical Society and member of the American Medical Association; also a pharmacist; on the staffs of the Grant and St. Elizabeth's hospitals and the City of Chicago Municipal Tuberculosis Sanitarium; died in Evanston (Ill.) Hospital June 10, aged 79, of primary bronchogenic carcinoma.

William Belitz, Cochrane, Wis.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898; died April 17, aged 81, of carcinoma of the gastrointestinal tract.

Oscar Caraker, Olmsted, Ill.; St. Louis College of Physicians and Surgeons, 1908; member of the American Medical Association; served as president of the Pulaski County Medical Society; on the staff of St. Mary's Hospital in Cairo; died May 22, aged 64, of coronary thrombosis.

Joseph Wallace Chetwynd, East Liverpool, Ohio; Jefferson Medical College of Philadelphia, 1907; member of the American Medical Association; on the staff of the East Liverpool City Hospital; formerly on the staff of the Massillon (Ohio) State Hospital; died May 2, aged 63, of heart disease.

Harold Thompson Clapp, Cleveland; University of Wooster Medical Department, Cleveland, 1890; medical examiner and consultant for the Travelers Insurance Company; died in the Lakeside Hospital May 27, aged 76, of myocardial failure.

Milton Daily, Sioux City, Iowa; Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1895; member of the American Medical Association; formerly police surgeon; served as a member and president of the city school board; at one time medical examiner for the Cudahy Packing Company and the Stock Yards Company; on the staff of St. Vincent's Hospital, where he died May 8, aged 74, of embolism of the lung, fracture of the femur and diabetes mellitus.

Richard Ensign Dickson ⊕ Holyoke, Mass.; Jefferson Medical College of Philadelphia, 1895; served as president of the Eastern Hampden Medical Association; on the staff of the Holyoke Hospital; died in the Wesson Memorial Hospital, Springfield, May 9, aged 78, of coronary thrombosis.

Ernest De Forest Hammond, Salt Lake City; John A. Creighton Medical College, Omaha, 1900; member of the American Medical Association; past president of the Salt Lake County Medical Society; president of the medical staff of the Holy Cross Hospital medical staff and served as chief surgeon for the Salt Lake and Utah Railroad Company; died in the Veterans Administration Facility May 1, aged 74, of coronary heart disease with decompensation.

Walter Childs Haviland ⊕ Mansfield Depot, Conn.; Baltimore Medical College, 1904; specialist certified by the American Board of Psychiatry and Neurology, Inc.; member of the American Psychiatric Association and the New England Society of Psychiatry; in 1939 joined the staff of the Mansfield State Training School and Hospital, where he recently retired as senior physician; served on the staffs of the Connecticut State Hospital in Middletown, Conn., and the Worcester Insane Hospital, Worcester, Mass.; died May 14, aged 63, of heart disease.

Claude Turner Keyes, San Angelo, Texas; Memphis (Tenn.) Hospital Medical College, 1897; member of the American Medical Association; died in a local hospital May 8, aged 74, of carcinoma of the liver.

Jesse B. Lampton ✠ Sapulpa, Okla.; Hospital College of Medicine, Louisville, Ky., 1907; died March 28, aged 66, of coronary heart disease.

Daniel Isaiah Leatherman ✠ Greensburg, Pa.; College of Physicians and Surgeons, Baltimore, 1886; died March 31, aged 84, of angina pectoris.

Francis X. McCormick, Milwaukee; Marquette University School of Medicine, Milwaukee, 1925; member of the American Medical Association; police surgeon and an examining physician for the state athletic commission; died in St. Mary's Hospital May 18, aged 47, of cerebral hemorrhage and arterial hypertension.

Arthur Willis McDonough, Denver; the Hahnemann Medical College and Hospital, Chicago, 1910; member of the American Medical Association; served as president and secretary of the Colorado *Homeopathic Society*; died April 11, aged 66, of cerebral tumor.

Edward Lee McIntyre, Springfield, Ky.; Kentucky School of Medicine, Louisville, 1889; died April 15, aged 81, of bronchopneumonia.

Ralph J. Melman ⊕ Philadelphia; Medico-Chirurgical College of Philadelphia, 1907; on the staffs of the Babies' and Northern Liberties hospitals; examining physician for the local draft board number 9; died April 10, aged 60, of coronary occlusion.

Francis A. Bernard Norton, Bakerstown, Pa.; University of Louisville (Ky.) Medical Department, 1902; died in the Schenley Nursing Home, Pittsburgh, March 14, aged 72, of arteriosclerotic heart disease and cerebral hemorrhage.

Gurdon Edgar Padget, Cuyler, N. Y.; Syracuse University College of Medicine, 1904; died May 4, aged 78, of coronary occlusion.

August Nob Pelusio, Paterson, N. J.; College of Physicians and Surgeons, Baltimore, 1913; died April 29, aged 64, of pulmonary edema and arteriosclerosis

Everett Clifton Perkins, Dover, N. H.; Medical School of Maine, Portland, 1897; died April 3, aged 74, of cerebral hemorrhage.

Allan Ramsey, Cincinnati; Medical College of Ohio, Cincinnati, 1896; formerly assistant professor of medicine at the University of Cincinnati College of Medicine; served on the staff of the Children's Hospital; died in the Christ Hospital April 10, aged 75, of a fractured skull caused by a fall on a street car.

William Ford Richardson, Beech Creek, Ky.; Louisville Medical College, 1904; member of the American Medical Association; on the staff of the Muhlenberg Community Hospital in Greenville, where he died May 10, aged 74, of heart disease.

Silas M. Rohr, Santa Rosa, Calif.; Baltimore Medical College, 1889; died April 16, aged 84, of chronic myocardial degeneration and herpes zoster.

Reed Alonzo Sauter ⊕ Schenectady, N. Y.; Albany Medical College, Albany, 1895; also a pharmacist; died March 7, aged 75, of coronary occlusion.

***John Gottleib* Schwarz,** Gallipolis, Ohio; Ohio-Miami Medical College of the University of Cincinnati, 1912; served as superintendent of the Ohio Hospital for Epileptics, where he had been assistant superintendent and for many years on the staff; died in the Holzer Hospital April 19, aged 70, of chronic nephritis.

William Dodds Scott Jr., Baltimore; University of Maryland School of Medicine, Baltimore, 1904; served overseas during World War I; formerly affiliated with the U. S. Public Health Service; died in the Union Memorial Hospital April 16, aged 66, of congestive heart disease and hypertensive cardiovascular disease.

Beryl Whittier Scully, Rome, N. Y.; Cornell University Medical College, New York, 1933; member of the American Medical Association; interned at the Bellevue Hospital in New York; died April 28, aged 39, of a fractured skull received when his automobile hit a tree.

George F. Seiberling ⊕ Allentown, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1893; on the staff of the Sacred Heart Hospital; member of the chamber of commerce; elected vice president of the board of directors of the Lehigh County Agricultural Society; died May 6, aged 75, of coronary thrombosis.

Arthur C. Sidler, Cudahy, Wis.; Milwaukee Medical College, 1897; formerly mayor of Cudahy; before Cudahy became a city he served as president of the village school board and health commissioner; died in Nashville, Tenn., March 31, aged 71, of arteriosclerotic heart disease.

Raymond Robinson Simmons ⊕ Winston-Salem, N. C.; Medical College of Virginia, Richmond, 1917; on the courtesy staffs of the City Memorial and North Carolina Baptist hospitals; died May 5, aged 53, of aortic and myocardial insufficiency.

Henry Petway Spencer, Burns, Tenn.; University of Tennessee Medical Department, Nashville, 1907; died in White Bluff April 18, aged 67, of coronary thrombosis.

Richard Henry Stafford, Sumner, Iowa; Rush Medical College, Chicago, 1890; for many years city health officer; surgeon for the Chicago Great Western Railway; died April 8, aged 85, of cardiovascular disease and coronary thrombosis.

Nevin G. Stevenson, Sparta, Ill.; Chicago Homeopathic Medical College, 1895; member of the American Medical Association; superintendent and owner of the Sparta Community Hospital, where he died April 28, aged 74, of cerebral hemorrhage.

Charles C. Stockard, Lawrenceburg, Tenn. (licensed in Tennessee in 1909); member of the American Medical Association; past president of the Hardin-Lawrence-Lewis-Perry-Wayne Counties Medical Society; at one time company physician for the Napier Irons Works in Napier; commissioned a first lieutenant by Governor Prentice Cooper as examining physician for the National Guard; died May 6, aged 60, of pernicious anemia.

Robert Glenn Stone, Atlanta, Ga.; University of Georgia Medical Department, Augusta, 1906; member of the Medical Society of New Jersey, American Medical Association and the American Psychiatric Association; in 1919 joined the staff of the New Jersey State Hospital, Trenton, where he was for many years clinical director, and from 1930 until he retired on May 1, 1944 medical director; died April 27, aged 64, of cardiac decompensation and renal insufficiency.

Colletta Mayme Swaney, Detroit; Wayne University College of Medicine, Detroit, 1937; served an internship at the Eloise Hospital in Eloise, Mich., and a residency at the East Side General Hospital; found dead in her apartment April 18, aged 40, of heart disease, acute venous stasis, emphysema of the lungs and congestion of the kidneys.

John W. Swindell, Greenville, Texas; Memphis (Tenn.) Hospital Medical College, 1892; member of the American Medical Association; died April 20, aged 75.

Thomas F. Taylor, Dresden, Tenn.; University of Tennessee Medical Department, Nashville, 1898; member of the American Medical Association; died in Martin April 4, aged 75, of coronary thrombosis.

Guglielmo A. Tedesco, Union City, N. J.; Regia Università di Torino Facoltà di Medicina e Chirurgia, Italy, 1899; died in St. Mary's Hospital, Hoboken, April 28, aged 70, of coronary occlusion and hypertrophy of the prostate.

Marcus Thrane, Hood River, Ore.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1894; member of the American Medical Association; died April 10, aged 70, of coronary thrombosis.

Joel Adams Tilton Jr. [illegible] George Washington University School [illegible] 1916; associated with the Veterans [illegible] April 28, aged 50, of coronary occlusion.

John Joseph Zaun Sr., Milwaukee; Rush Medical College, Chicago, 1901; on the staff of St. Mary's Hospital, where he died May 19, aged 65, of embolism.

PUBLIC HEALTH SERVICE

Leon Glassman ⊕ Assistant Surgeon, U. S. Public Health Service Reserve, Philadelphia; Hahnemann Medical College and Hospital, Philadelphia, 1940; interned and served a residency in obstetrics and gynecology at the Hahnemann Hospital in Philadelphia; entered the public health service reserve as assistant surgeon and began active duty in October 1943; assigned to the outpatient department of the U. S. Marine Hospital, Baltimore; on May 5, 1944 transferred to the War Shipping Administration and assigned to the medical examination program; later in 1944 assigned to the U. S. Maritime Service Training Ship *American Engineer;* a short while later ordered to the Coast Guard, Captain of the Port, Baltimore; assigned to the District Coast Guard office, Sixth Naval District, Charleston, S. C., for the final tour of duty on Oct. 30, 1944, since which time he had been on sea duty with the Coast Guard as medical officer aboard a Coast Guard cutter; recommended for the Purple Heart; was buried in the Marine cemetery on Saipan; died May 4, aged 30, of injuries received when he slipped on the Jacob's ladder while helping load wounded marines aboard his ship.

Correspondence

METHYLENE BLUE TEST FOR BILIRUBIN IN THE URINE

To the Editor:—The editorial comment in THE JOURNAL, April 21, page 1059, discussed Myers' use of the methylene blue test for bilirubin in the urine. In Correspondence May 26, page 308, appeared a communication from Watson, Meads and Castle in which the value of the test as used by Myers was questioned because of its lack of specificity for bilirubin. For the past one and one-half years the methylene blue test has been under investigation in several laboratories engaged in the study of infectious hepatitis under the auspices of the Commission on Measles and Mumps, Army Epidemiological Board, Preventive Medicine Service, Office of the Surgeon General, U. S. Army. Our experience with a modified methylene blue test in several epidemics of infectious hepatitis and in hepatitis produced experimentally in human volunteers has indicated that the modified test is capable of providing valuable information concerning the presence of bilirubin in the urine. A brief discussion of the technic and interpretation of the methylene blue test, as used in our studies, may aid in reconciling the favorable experience of Myers with the unfavorable opinion expressed by Watson, Meads and Castle. The test was performed by Myers and by Watson and her associates by adding 2 drops of methylene blue to 10 cc. of urine. The occurrence of a green color apparently has been interpreted as a positive test for bilirubin in the urine. Unfortunately, experience has shown that the addition of 2 drops of methylene blue to certain urines which do not contain bilirubin is followed by the development of a green color. Our experience indicates that this objection to the test can be eliminated by modifying the technic and interpretation.

The cause of the green color produced by the addition of methylene blue to certain urine specimens has been subject to controversy since the beginning of the century. Experiments such as those described by Watson and her associates indicate that the blending of the yellow pigments of urine, regardless of their nature, with methylene blue (or other blue solutions) produces a green color. This is the explanation for the green color occurring after the addition of 1 to 4 drops of methylene blue to certain urines that do not contain bilirubin. However, tests of a large number of supposedly normal and pathologic urines have indicated that no commonly occurring urine pigments other than bilirubin produce sufficient yellow color to require more than 4 drops of methylene blue to extinguish the green color resulting from the blending of blue and yellow.

For this reason we have performed and interpreted the test as follows: An aqueous solution of methylene blue (0.2 per cent based on actual dye content) is added drop by drop to 5 cc. of urine and the total number of drops required to impart a blue color to the urine-methylene blue mixture is noted. If more than 8 drops are required a smaller measured amount of urine is diluted to 5 cc. and the test repeated in order that a clearer end point may be obtained. If diluted, the number of drops is multiplied by the dilution factor. The reading (in drops) is taken as one less than the number needed to change the color from green to blue. A reading greater than 4 drops has been regarded as a positive test for bilirubin in the urine. Although the sensitivity of the test was diminished by the use of this criterion, its specificity was increased greatly, as indicated by the infrequent occurrence of falsely positive tests. Readings of 2 to 4 drops inclusive have been regarded as suggestive and as an indication for additional studies. As already stated, our investigations of this modified methylene blue test have been confined almost entirely to the study of urines from patients with infectious hepatitis. In this condition the modified test has yielded information of considerable value both in respect to early diagnosis and as a simple means of following the course of the disease. Furthermore, positive tests have been obtained with the urines from many hepatitis patients before the appearance of overt jaundice. An additional contribution of the test has been the roughly quantitative information it provides concerning changes in the excretion of bilirubin in the urine.

The methylene blue test, in our experience, has been inferior in sensitivity and specificity to the Harrison and diazo "spot" tests for bilirubin in the urine. On the other hand, when positive, it provides better quantitative evidence concerning the output of urine bilirubin than is afforded by the "spot" tests and it can be performed under conditions which do not permit the use of the latter. For these reasons it is our opinion that the modified methylene blue test, properly used and interpreted, will prove to be a valuable procedure.

Conclusive evidence has been obtained (by J. G. Reinhold and others) that a chemical reaction occurs between methylene blue and bilirubin. Spectrophotometric studies have revealed alterations in the absorption spectrums of methylene blue and bilirubin when the two were combined in aqueous solution. Furthermore, a green precipitate was obtained by the addition of methylene blue to bilirubin in weakly alkaline solutions. A similar precipitate appeared on standing after adding methylene blue to neutral or weakly alkaline urines containing bilirubin (obtained from patients with hepatitis). However, it is believed that this chemical reaction is less important than the blending of blue and yellow colors in explaining the green color constituting the positive methylene blue test.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and Examining Boards in Specialties were published in THE JOURNAL, July 7, page 762.

BOARDS OF MEDICAL EXAMINERS

ALASKA: Juneau, September. Sec., Dr. W. M. Whitehead, Box 561, Juneau.

CALIFORNIA: *Oral.* Los Angeles, Aug. 11. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento 14.

CONNECTICUT: * *Endorsement.* New Haven, July 24. Sec. to the Board, Dr. Creighton Barker, 258 Church St., New Haven.

DELAWARE: *Reciprocity.* Dover, July 17. Sec., Medical Council of Delaware, Dr. J. S. McDaniel, 229 S. State St., Dover.

INDIANA: Indianapolis, Aug. 28-30. Sec., Board of Medical Registration & Examination, Dr. W. C. Moore, 301 State House, Indianapolis 4.

MONTANA: Helena, Oct. 1-3. Sec., Dr. O. G. Klein, First Nat'l. Bank Bldg., Helena.

NEVADA: *Reciprocity.* Carson City, Aug. 6. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

NEW MEXICO: * Santa Fe, Oct. 8-9. Sec., Dr. LeGrand Ward, 141 Palace Ave., Santa Fe.

OHIO: *Endorsement.* Columbus, July. Sec. Dr. H. M. Platter, 21 W. Broad St., Columbus.

OREGON: * Portland, July 25-27. Exec. Sec., Miss L. M. Conlee, 608 Failing Bldg., Portland 4.

SOUTH DAKOTA: * Pierre, July 17-18. Sec., Medical Licensure, State Board of Health, Dr. Gilbert Cottam, State Capitol, Pierre.

TEXAS: Houston, July 17-19. Sec., Dr. T. J. Crowe, 918-20 Texas Bank Bldg., Dallas 2.

WASHINGTON: * Seattle, July 16-18. Sec., Department of Licenses, Miss Nell Adams, Olympia.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

MICHIGAN: Ann Arbor and Detroit, Oct. 12-13. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing.

NEBRASKA: Omaha, Oct. 2-3. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Bldg., Lincoln 9.

RHODE ISLAND: Providence, Aug. 15. Chief, Division of Examiners, Mr. Thomas Casey, 366 State Office Bldg., Providence.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

*Tumors of Thymus in Myasthenia Gravis. N. A. Murray and J. R. McDonald.—p. 87.
*Rh Antibodies. I. Davidsohn.—p. 95.
Rh Blood Types and Some of Their Applications. A. S. Wiener. —p. 106.

Tumors of Thymus in Myasthenia Gravis.—Murray and McDonald studied thymus glands removed from 10 fetuses and from 100 persons from the ages of 4 months to 86 years. They also studied thymomas associated with myasthenia gravis in 13 cases and 2 thymic tumors removed surgically from patients with myasthenia gravis. Several observations made by them suggested that these tumors are thymomas. Most primary tumors of the thymus associated with myasthenia gravis are of a single type. They are made up of lymphocytes and larger pale cells that have faintly acidophilic cytoplasm in varying proportions and indefinite cell boundaries. These tumors contain numerous small blood vessels and occasional Hassall's corpuscles. A "lining up" or palisading of the pale cells along connective tissue trabeculae and pseudorosette formation around blood vessels appear to be distinguishing features. If metastasis and direct extension are sufficient criteria for the diagnosis of malignancy, then these tumors are malignant. It is believed that "thymoma" is an adequate name for these tumors. Those which will metastasize cannot be distinguished from those which will not metastasize. The absence or presence of secondary germ centers (lymph follicles) does not point either to or away from malignancy. The absence of differentiation between cortex and medulla is not a reliable criterion for the diagnosis of malignancy. The incidence of myasthenia gravis among patients with thymoma is nearly 100 per cent. Eaton has stated that the incidence of thymomas among patients with myasthenia gravis is 14 per cent. According to Bell the incidence at necropsy of thymic dysplasia among patients who have died of myasthenia gravis is about 50 per cent.

Rh Antibodies.—Davidsohn says that the titer of anti-Rh agglutinins in the blood of mothers of children with erythroblastosis is highest from about eight to twenty days following delivery, and this is the best time for testing for anti-Rh agglutinins and for obtaining potent anti-Rh serum. The prozone phenomenon (failure of antigen-antibody reaction in undiluted serum, but manifest reaction in higher dilutions) is not infrequent in anti-Rh serum. Therefore, when testing for anti-Rh agglutinins, serum dilutions up to 1:20 should be examined. The presence of anti-Rh agglutinins during pregnancy does not necessarily spell erythroblastosis in the baby about to be born, particularly if the antibodies may be ascribed to a preceding pregnancy. Erythroblastosis may be due to Rh incompatibility even in case of Rh-positive mothers. Among factors of possible prognostic significance with regard to future pregnancies, the following two considerations may have to be included: (*a*) the homozygocity or heterozygocity of the husband if determinable; (*b*) the persistence of anti-Rh agglutinins following birth of a child with erythroblastosis.

Sulfathiazole-Cod Liver Oil Ointment in Postoperative Care of Septic Hand. D. Brezin.—p. 232.

Fatal Air Embolism Due to Powder Insufflators.—Martland investigated two deaths occurring after vaginal insufflation of medicinal powders for the relief of pruritus vulvae. In the first case a virginal and cribriform hymen played an important role in the causation of the air embolism. The doctor, believing he was spraying powder over the external genitals, must have unknowingly held the glass tip of the insufflator directly over the largest opening in the hymen and have blown powder and air into the vagina. The air entrapped in the vagina was forced into the uterine cavity. The exact point of entry of air into the venous circulation cannot be demonstrated. The fact that the patient had just passed a menstrual period favors engorgement and distention of the uterine veins. The second woman was six months pregnant. In this case the metal end of the insufflator must have rested against the soft cervix of the pregnant uterus and considerable powder and large amounts of air were blown directly into the uterine cavity. The main purpose of the insufflators is to dilate and smooth out the folds

in the vagina so that the powder may be sprayed on the mucosa. It is obvious that the sudden blowing up of the vagina with air under excessive pressure is not without danger. The engorgement of the endometrium around the menstrual period, open veins after uterine curettage and the soft cervix of a pregnant uterus all might favor air embolism during such insufflations. It is reasonable to assume that few of these catastrophes are likely to be reported and that perhaps some such deaths have been attributed to heart disease or some other condition and never verified by necropsy.

Positive Pressure Respiration for Pulmonary Edema.—Ansbro reports 2 cases of acute pulmonary edema in which positive pressure respiration with oxygen was followed by a prompt clearing of the condition and recovery. The first patient took an overdose of sedative medication the night and morning before operation. Respiratory depression following the operative procedure was considered the initial cause of the widespread pulmonary edema that ensued. Inhalation of oxygen by catheter, mask and tent failed to relieve either the cyanosis or the edema. The application of positive pressure by the anesthesia mask resulted in a swift clearing of edema and cyanosis. The pulmonary edema in the second patient probably resulted from the primary tracheal obstruction (which necessitated the tracheotomy) and was aggravated by the ensuing ball valve action of the wet gauze at the tube opening, which resulted in an increased negative intrapulmonary pressure. The removal of the ball valve produced some improvement; the patient was literally "drowning in her own secretions" until positive pressure respiration dammed back the fluid. It is recommended that positive pressure respiration be adopted in combating what is frequently regarded as a terminal event.

Venesection for Plethoric Patient. L. E. Hines and D. L. Kessler.—p. 248.

Effects of Cold on Air Passages.—Moritz and Weisiger caused dogs to breathe extremely cold air for periods ranging between twenty and one hundred and thirty-three minutes. The rate at which air was warmed within the body was measured by means of appropriately placed thermocouples. The air was delivered to the larynx at temperatures which ranged between —50 and —28 C., and in no instance were temperature recordings lower than +18 C. observed at the bifurcation of the trachea. The explanation of the rapid warming of inhaled cold air and of the occurrence of relatively mild and localized injury following the inhalation of cold air lies in the fact that dry air has an extremely low heat capacity and that the number of calories required to produce a great rise in the temperature of dry air can be provided by the heat derived from the cooling of a small amount of tissue by a few degrees. Although the intermittent exposure to cold air that occurs during normal respiration does not cause significant injury to the pharynx or larynx, a continuous exposure of these structures to cold may result in the development of a rapidly obstructive edema. Experiments on dogs warrant the inference (1) that it is unlikely that significant injury to the air passages of man would result from the breathing of air at any degree of coldness likely to be encountered in nonexperimental conditions as long as it was inhaled through the nose or between partially closed lips and (2) even though extremely cold air was inhaled rapidly through a widely opened mouth, it would be warmed to a point well above freezing by the time it reached the bronchi.

Fatal Poisoning with Potassium Thiocyanate.—Del Solar and his associates gave potassium thiocyanate to 73 patients with hypertension. In the fatal case which they report a distinct fault in dosage on the part of the patient was responsible for the intoxication. The case emphasizes the danger of prescribing the drug in easily inaccurately measured forms, like the solution for drop administration. The thiocyanate concentration of the blood at the onset of toxic symptoms was only 7 mg. per hundred cubic centimeters. The concentrations of the drug in the tissues are the highest ones thus far reported in similar instances. A prominent feature of the postmortem examination was the finding of an acute necrotic nephrosis that had produced no symptoms or signs during life.

Pyridoxine (Vitamin B_6) in Granulocytopenia.—Cantor and Scott point out that the list of drugs likely to cause granulocytopenia has been lengthened year by year and now includes a number of coal tar derivatives, the barbiturates, the sulfonamides, gold salts and thiouracil. They report 3 cases of granulocytopenia successfully treated with pyridoxine (vitamin B_6). The pyridoxine was given daily by intravenous injection in doses of 125 or 200 mg. The material used was a 10 per cent solution of pyridoxine hydrochloride in isotonic solution of sodium chloride. This was put up in 10 cc. rubber capped vials and autoclaved for thirty minutes at 15 pounds pressure. The rapid and uniform response observed in these cases leads the authors to suggest that pyridoxine is the factor in liver and liver extracts responsible for the granulocytopoietic effect noted when liver is administered in granulocytopenia. Pyridoxine

produces granulocytopoiesis by an effect of the myelocytic elements of the bone marrow. It seems probable that pyridoxine is the factor involved in the maturation and emigration of the polymorphonuclear leukocyte.

Some Observations of Changes in Renal Water Output of Albino Rat Under Influence of High Fat Diet. H Shay, R. Kolm and S S. Fels—p 257.

Effect on Liver of Atabrine Dihydrochloride (Quinacrine Hydrochloride).—Butt and his associates administered to 50 white men between the ages of 19 and 35 years 4 5 Gm of atabrine over a ten day period. All of these patients had had malaria with multiple relapses. Prior to the administration of atabrine and again at the completion of the ten day course of atabrine therapy the following laboratory procedures were carried out: (1) sulfobromophthalein test for hepatic function; (2) prothrombin time (Quick's method); (3) serum bilirubin; (4) van den Bergh reaction; (5) erythrocyte, leukocyte and differential count; hemoglobin estimation and a special blood smear for macrocytosis; (6) thick blood smear for malaria parasites. There was little evidence that atabrine exerted much, if any, hepatotoxic action. The toxic reactions reported in this and other studies have been few and of only moderate severity. To hesitate to use atabrine because of the possible untoward reactions does not seem justified.

Wound Infections in Diabetic Surgical Patients.—Watson presents observations on 34 patients with a history of preceding diabetes mellitus who were operated on for some pathologic condition having no direct relation to their glycosuria. The diabetes was well controlled in these patients. With the exception of two thyroidectomies and one hernioplasty, every patient was subjected to laparotomy. Fifteen of the wounds healed by primary union; 19 of the wounds became infected. A comparative study of operative wounds of an equal number of nondiabetic surgical patients was made for control purposes. Wound infections developed in 3 of the 34 cases selected. Postoperative wound infections were almost six times more frequent in the diabetic group. This susceptibility is in large part due to the greatly lowered tissue resistance inherent in the diabetic patient.

Injuries to Peripheral Nervous System in War.—Naffziger thinks that under the best conditions the results of surgery of the peripheral nerves leave much to be desired. The functional result depends on the integrity of the entire neuromuscular mechanism. Much more is involved than merely regeneration of a nerve. Muscles destroyed or fibrosed cannot act even though nerve supply returns. Injuries to major vessels with ischemia, when associated with palsies of the nerves, constitute one of the most severe conditions. We have little to offer the victims of traction injuries in which, through stretching, the damage to fibers is spread over great lengths of the nerve. The affected nerve, though remaining in gross continuity, contains widely scattered areas of rupture and degeneration. Suture of nerves is time consuming and is not practicable in the rush of urgent war surgery. It is a sound surgical principle to allow considerable time after complete healing of a wound before repair of a nerve is attempted. As regards organization of our medicomilitary establishment, we have profited neither from our experiences in the last war nor from the example of our British allies. British military forces are cared for by 3.5 medical men per thousand, as compared to about 6.0 used by our army. More highly specialized care is being given by the English than is available to our forces, in spite of the fact that Great Britain has proportionately fewer medical men. They have accomplished this without waste of medical manpower by utilizing existing facilities. Of the five British peripheral nerve centers, four are associated with or are near medical schools. They are staffed principally by civilians. In addition to the surgeon, neurologists, neurophysiologists, neuropathologists, orthopedists and special technical help from the medical schools participate and form a team. Among the directing surgeons are some who had a vast experience in this type of surgery in the last war. In the United States, three years of war have resulted in the designation of certain general hospitals for peripheral nerve cases. The specialized staffs consist of young neurologic surgeons, mostly well trained in the fundamentals of the specialty but without previous opportunity to familiarize themselves with the diagnosis and therapy of injuries to peripheral nerves. If the hospitals were located near medical schools, the staffs of these schools would supplement the study and care of the patients and, in addition, the military hospitals would serve as training centers for the specialists of tomorrow. Such opportunities cannot be duplicated and should not be lost.

*Penicillin in Treatment of Gonorrhea. D. R. Seabaugh.—p. 273.
*Diagnosis of Thromboangiitis Obliterans and Peripheral Arteriosclerosis. P. S. Lowenstein.—p. 277.

Penicillin in Treatment of Gonorrhea.—Seabaugh found that 100,000 units of penicillin is productive of cures in 74.3 per cent of cases of gonorrhea. This percentage of cures may be increased to 95 by the administration of additional penicillin. Five per cent of the cases treated did not respond to 400,000 units of the drug. The effectiveness of penicillin is not dependent on the age or chronicity of the lesion. After a clinical and bacteriologic cure, 6.1 per cent of the total cases treated will undergo a relapse within the first ten days. Another 11.9 per cent of the total cases treated will show a primary reduction of the discharge to only a morning tear with negative prostatic cultures and also undergo a relapse back to an active status. Penicillin exerts no demonstrable effect on acute epididymitis. When given intramuscularly, it produced no demonstrable improvement in 2 cases of gonorrheal rheumatism. Direct administration of 25,000 units of the drug quickly controlled the acute inflammatory manifestations in an acutely involved knee. Penicillin administered locally will cure some cases of anterior gonorrheal urethritis but is less effective than by the intramuscular route.
